Clinical Trials: NCCN believes that the best management for any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

To find clinical trials online at NCCN Member Institutions, click here: nccn.org/clinical_trials/physician.html.

NCCN Categories of Evidence and Consensus: All recommendations are category 2A unless otherwise specified.

See NCCN Categories of Evidence and Consensus.
Updates in the 2.2014 Version of the NCCN Guidelines for Adult Cancer Pain from the 1.2014 Version include:

**MS-1**
- The discussion section was updated to reflect the changes in the algorithm.

---

Updates in Version 1.2014 of the NCCN Guidelines for Adult Cancer Pain from Version 2.2013 include:

**PAIN-1**
- Principles of Cancer Pain Management
  - Principles were separated into 4 difference sections: General, Assessment, Management/Intervention, and Reassessment.
  - Under Management/Intervention,
    - 1st bullet was revised by adding: “Goals of pain management are improved comfort, function, and safety.”
    - 5th bullet was added: “For acute pain crisis, consider hospital admission to achieve patient-specific pain goals.”
    - 6th bullet was added: “Persistent cancer pain often requires treatment with regularly scheduled analgesics, and supplemental doses of analgesics are often required to manage breakthrough pain.”
    - 7th bullet was added: “For chronic pain in cancer survivors, see NCCN Guidelines for Survivorship.”

**PAIN-2**
- Pain related to an oncologic emergency
  - “Epidural metastases and “leptomeningeal metastases” were removed and replaced by “Neuroaxial metastases with threatened neural injury.”
  - Footnote “c” was added: “For chronic pain in cancer survivors, see NCCN Guidelines for Survivorship. Also for PAIN-5.

**PAIN-3**
- For all pain levels
  - 8th bullet was added: “For acute pain crisis, consider hospital admission to achieve patient-specific pain goals.”
  - The “goal of treatment” statement was revised by adding: “Reevaluate pain at each contact and as needed to meet patient-specific goals for comfort, function, and safety.” Also for PAIN-6 and PAIN-7.

**PAIN-4**
- For pain ≥ 4, “moderate to severe” was added as another descriptor. Also for PAIN-5.

**PAIN-7**
- Ongoing care
  - 1st bullet was modified: “Convert from parenteral to oral/transdermal medications (if feasible) including extended-release or long-acting agent with rescue doses...”
  - 9th bullet was revised from “Process realistic goals, revise, and review” to “Reevaluate patient-centered goals of care in the context of current disease and available therapies”

**PAIN-C 1 of 3**
- Pain experience
  - Current pain management plan, if medications are used, “route of administration” was added as a question to determine.

**PAIN-C 3 of 3**

**PAIN-D**
- Bone pain without oncologic emergency
  - 2nd sub-bullet, “denosumab” was added as an example of a bone-modifying agent.
  - 4th sub-bullet: “radiofrequency ablation” was added as an example to treat local bone pain.
  - Nerve pain
    - Refractory pain, “trial of opioid” was removed.

Continued on next page
NCCN Guidelines Version 2.2014 Updates
Adult Cancer Pain

Updates in Version 1.2014 of the NCCN Guidelines for Adult Cancer Pain from Version 2.2013 include:

PAIN-E 1 of 10
- General Principles
  - 7th bullet was revised as: “Steady state drug levels will be achieved when a stable drug dose has been routinely administered for a period equal to 5 times the drug elimination half life in about 5 half lives.”
  - 8th bullet was revised as: “If pain improves, it is important to look for opportunities to reduce opioid dose and optimize use of nonopioid analgesics as possible without compromising pain control. Where appropriate, if opioid dose reduction is desired or indicated, consider opioid dose reduction could be reduced by 10%-25% with subsequent reevaluation and further dose adjustment.”
  - 9th bullet was revised: “If patient is experiencing unmanageable adverse effects and pain is moderate to severe, consider downward dose titration by approximately 10%-25% and reevaluate.”

PAIN-E 2 of 10
- Opioids and Risk Evaluation and Mitigation Strategy (REMS)
  - 1st sub-bullet, 1st tertiary bullet was changed from “Prescriber should establish opioid analgesic goals of therapy for each patient and regularly evaluate therapeutic opioid response to guide further therapy” to “Patient’s therapeutic response to opioid therapy should be regularly evaluated as to patient treatment goals of therapy.”
  - Last sub-bullet was updated from “...all transmucosal fentanyl products, transdermal fentanyl products, and transdermal buprenorphine (See Approved Risk Evaluation and Mitigation Strategies [REMS]), and in 2013 the FDA will introduce REMS starting with continuing education for morphine-naltrexone combination product, all extended-release opioids, and long-acting opioids (methadone). See FDA questions and answers for REMS for extended-release and long-acting opioid analgesics” to “REMS programs are currently in place for: All transmucosal fentanyl products and Long-acting, extended-release formulations, hydromorphone, morphine, oxycodone, oxymorphone, tapentadol, methadone tablets and solutions that are indicated for use as analgesics, fentanyl or buprenorphine-containing transdermal delivery systems.”
  - 3rd bullet was revised by adding: “...excluding methadone due to its long duration of effect.”

PAIN-E 3 of 10
- 3rd bullet was revised by adding: “...excluding methadone due to its long duration of effect.”

PAIN-E 4 of 10
- Table 1: “Levorphanol” was removed from the table.
- Footnote “5” was modified as: “Long half-life, observe for drug accumulation and adverse effects, after 2-5 days especially over first 4-5 days. In some individuals, steady state may not be reached for several days to 2 weeks. Methadone is typically dosed every 8-12 h. May need to be dosed every 4 h initially then changed to every 6-8 h.”
- Footnote “8” was modified as: “Codeine has no analgesic effect unless it is metabolized into morphine, morphine-6-glucuronide by hepatic enzyme CYP2D6. Individuals with low CYP2D6 activity may receive no analgesic effect from codeine, but rapid metabolizers may experience toxicity from higher morphine production. Therefore, in the 10%-30% of individuals in whom metabolism is ineffective, codeine would have no analgesic effect and should be avoided.

PAIN-E 5 of 10
- Partial agonist
  - Transdermal buprenorphine bullet was modified by adding: “Conversion to buprenorphine from other opioids may be complex; consider a pain specialty consultation.”

PAIN-I 1 of 2
- Patient and Family/Caregiver Education
  - Messages to be conveyed to patient and family/caregiver regarding the proper disposal of unused or unneeded medications (especially opioid analgesics), the following two bullets were revised:
    - “Per the FDA, unless a take-back drug program is immediately available, the recommendation is in general, advise not to flush excess opioids down sink or toilet.
    - Check with local pharmacy or law enforcement about proper medication disposal.”

Continued on next page
Updates in Version 1.2014 of the NCCN Guidelines for Adult Cancer Pain from Version 2.2013 include:

**PAIN-I 2 of 2**
- The following must be reviewed
  - 1st sub-bullet was revised: “Plan for obtaining refilled prescriptions, especially potent opioids, because schedule II narcotics that cannot be ordered by telephone.”

**PAIN-K 1 of 2**
- Acetaminophen
  - 1st bullet, the second sentence was changed from: “The FDA is currently evaluating daily maximum dosing and has considered the daily maximum dose for chronic use be limited to 3 g/d or less” to “For chronic administration, consider limiting the maximum daily dose to 3 g/d or less due to concerns for hepatic toxicity.”
- NSAIDs
  - 1st bullet was revised: “Use NSAIDs with caution, especially for chronic use, as many oncology patients may be at high risk for renal...”

**PAIN-K 2 of 2**
- Treatment of NSAID GI toxicities, the second sub-bullet was revised by removing, “Consider adding antacids, H2 receptor antagonists, misoprostol, or omeprazole” and adding, “As prophylaxis for NSAID peptic ulceration, consider adding misoprostol or protein pump inhibitors.”
- Further NSAID considerations, the following bullet was added: “The use of concomitant NSAID with prophylactic aspirin may reduce the effectiveness of aspirin. Therefore, it is recommended to either avoid use or take separately to avoid this possibility.”

**PAIN-M**
- Commonly used interventional procedures
  - Regional infusions, the following information was added:
    - Epidural: *use beyond several days to a few weeks is limited by concerns for catheter displacement and infection*
    - Intrathecal: *implanted infusion pumps may be costly, refills require technical expertise*
    - Regional plexus: *use beyond several days to a few weeks is limited by concerns for catheter displacement and infection*
  - Neurodestructive procedures for well-localized pain syndromes, the following was revised:
    - Head and neck: peripheral *neurolysis generally associated with sensory and/or motor deficit nerve-bleek*
Pain Definition

Pain is defined by the International Association for the Study of Pain (IASP) as an unpleasant, multidimensional, sensory, and emotional experience associated with actual or potential tissue damage, or described in relation to such damage.a

Principles of Cancer Pain Management

General

• There is increasing evidence in oncology that survival is linked to symptom control and that pain management contributes to broad quality-of-life improvement. b To maximize patient outcomes, pain management is an essential part of oncologic management.
• Analgesic therapy is done in conjunction with management of multiple symptoms or symptom clusters and the complex pharmacologic therapies that patients with cancer are generally prescribed.
• A multidisciplinary team may be needed.
• Psychosocial support must be available including both emotional and informational support and coping skills training. (See PAIN-H)
• Specific educational material must be provided to the patient and family/caregiver. (See PAIN-I)
• Consider the multidimensional impact of “suffering” on patients and their families and address these concerns in a culturally respectful manner.

Assessment

• All patients must be screened for pain at each contact. (See PAIN-2)
• Pain intensity must be quantified and quality must be characterized by the patient (whenever possible based on patient communication capacity).
• Comprehensive pain assessment must be performed if new pain is present and regularly performed for persisting pain. (See PAIN-C)
• Assessment of patient’s pain is essential with a rating scale but also includes patient reporting of qualities of the pain, breakthrough pain, treatments used and their impact on pain, patient reporting of adequate comfort, patient reporting of satisfaction with pain relief, provider assessment of adequacy of function, and any special issues for the patient relevant to pain treatment.

Management/Intervention

• Goals of pain management are improved comfort, function, and safety.
• Comprehensive pain management is needed as most patients have multiple pathophysologies and multiple symptoms.
• Prevention of expected analgesic side effects, especially constipation in the setting of opioid use, is key to effective pain treatment.
• Optimize patient and family education (See PAIN-I) and physical and cognitive integrative interventions (See PAIN-H and PAIN-J).
• For acute pain crisis, consider hospital admission to achieve patient-specific pain goals.
• Persistent cancer pain often requires treatment with regularly scheduled analgesics, and supplemental doses of analgesics are often required to manage breakthrough pain.
• For chronic pain in cancer survivors, see NCCN Guidelines for Survivorship.

Reassessment

• Reassessment of pain intensity must be performed at specified intervals to ensure that the analgesic therapy selected is having the maximum benefit with as few adverse effects as possible.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

See Universal Screening (PAIN-2)

---
Opioid-naive patients:

- Quantify pain intensity and characterize quality
  - See Pain Intensity Rating (PAIN-A)
- Severe uncontrolled pain is a medical emergency and should be responded to promptly

If pain present →

- Comprehensive pain assessment (See PAIN-C) in order to identify
  - Pain etiology
  - Pain pathophysiology
  - Specific cancer pain syndrome (See PAIN-D)
  - Patient goals for comfort and function

If pain present →

- Pain not related to an oncologic emergency
  - Opioid-tolerant patients
    - Pain Rating ≥4
      - See Management of Pain in Opioid-Tolerant Patients (PAIN-5)
    - or Pain Rating 0-3
      - See Procedure-Related Pain and Anxiety (PAIN-B)

Screen for pain →

- If no pain → Rescreen at each subsequent visit
- Anticipated painful events and procedures → See Procedure-Related Pain and Anxiety (PAIN-B)

Pain related to an oncologic emergency:

- Bone fracture or impending fracture of weight-bearing bone
- Neuroaxial metastases with threatened neural injury
- Infection
- Obstructed or perforated viscus (acute abdomen)

Analgesics as specified by above pathway in addition to specific treatment for oncologic emergency (e.g., surgery, steroids, radiation therapy [RT], antibiotics)

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

Opioid tolerant includes patients who are chronically receiving opioid analgesic on a daily basis. The FDA identifies tolerance as receiving at least 60 mg of morphine daily, at least 30 mg of oral oxycodone daily, or at least 8 mg of oral hydromorphone daily or an equianalgesic dose of another opioid for a week or longer.

</tr>
</tbody>
</table>

After 2-3 cycles, see PAIN-6 for subsequent management and treatment

See Subsequent Pain Management, Mild Pain 0-3 (PAIN-6)

---

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

---

**Opioid naïve** includes patients who are not chronically receiving opioid analgesic on a daily basis and therefore have not developed significant tolerance. The FDA identifies tolerance as receiving at least 60 mg of morphine daily, at least 30 mg of oral oxycodone daily, or at least 8 mg of oral hydromorphone daily or an equianalgesic dose of another opioid for a week or longer.

**Subcutaneous can be substituted for intravenous; however, peak effect subcutaneously is usually 30 min.**
MANAGEMENT OF PAIN IN OPIOID-TOLERANT PATIENTS

Monitor for acute and chronic adverse effects. (See Management of Opioid Adverse Effects, PAIN-F)

### Opioid-Tolerant Patients

#### Initial Dose
- **Oral (peak effect 60 min)**
  - Pain score unchanged or increased
  - Increase dose by 50%-100%
- **Intravenous bolus (peak effect 15 min)** or PCA
  - Pain score unchanged or increased
  - Increase dose by 50%-100%

#### Subsequent Dose
- Pain score unchanged or increased
  - Increase dose by 50%-100%

#### After 2-3 cycles, consider IV titration and/or see PAIN-6

### Note:
- All recommendations are category 2A unless otherwise indicated.
- Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

---

**For chronic pain in cancer survivors, see NCCN Guidelines for Survivorship.**

**Opioid tolerant includes patients who are chronically receiving opioid analgesics on a daily basis. The FDA identifies tolerance as receiving at least 60 mg of morphine daily, at least 30 mg of oral oxycodone daily, or at least 8 mg of oral hydromorphone daily or an equianalgesic dose of another opioid for a week or longer.**

**Subcutaneous can be substituted for intravenous; however, peak effect subcutaneously is usually 30 min.**

**Not including transmucosal fentanyl dose.**
**NCCN Guidelines Version 2.2014**
Adult Cancer Pain

**PAIN INTENSITY**

**See Pain Intensity Rating (PAIN-A)**

For **ALL** pain levels:

- For persistent pain, initiate regular schedule of opioid with rescue dose as needed
- Continue management of constipation (See PAIN-F)
- Provide psychosocial support (See PAIN-H)
- Provide patient and family/caregiver education (See PAIN-I)
- Optimize integrative interventions (See PAIN-J)

---

**Severe Pain 7-10**

- See management for **all** pain levels above AND
- Reevaluate opioid titration (See PAIN-E)
- Reevaluate working diagnosis with a comprehensive pain assessment (See PAIN-C)
- Consider specific pain syndrome problems (See PAIN-D)
- Consider pain specialty consultation (See PAIN-L)
- Reevaluate adjuvant analgesics as indicated (See PAIN-G)

---

**Moderate Pain 4-6**

- See management for **all** pain levels above AND
- Continue opioid titration (See PAIN-E)
- Consider specific pain syndrome problems (See PAIN-D)
- Consider pain specialty consultation (See PAIN-L)
- Continue adjuvant analgesic titration (See PAIN-G)

---

**Mild Pain 0-3**

- See management for **all** pain levels above AND
- Reassess and modify regimen to minimize adverse effects (See PAIN-E and See PAIN-F)
- Adjuvant analgesics as needed (See PAIN-G)

---

**GOALS OF TREATMENT**

**SUBSEQUENT PAIN MANAGEMENT**

Reevaluate pain at each contact and as needed to meet patient-specific goals for comfort, function, and safety

Achieved → See Ongoing Care (PAIN-7)

Not achieved →

- See Universal Screening and Assessment (PAIN-2)
- Consider pain management specialty consultation.
- Consider interventional strategies (PAIN-M) or other treatments
- Consider palliative care consultation (See NCCN Guidelines for Palliative Care)

---

*Opioid tolerant includes patients who are chronically receiving opioid analgesic on a daily basis. The FDA identifies tolerance as receiving at least 60 mg of morphine daily, at least 30 mg of oral oxycodone daily, or at least 8 mg of oral hydromorphone daily or an equianalgesic dose of another opioid for a week or longer.*

---

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
**ONGOING CARE**

- Convert from parenteral to oral/transdermal medications (if feasible) including extended-release or long-acting agent with rescue doses (Conversion details, see PAIN-E)
  - Simplify analgesic regimen for improved patient compliance, if feasible.

- Routine follow-up
  - Assess pain during each outpatient contact or at least each day for inpatients or more frequently based on:
    - Patient’s condition
    - Institutional standards
    - Regulatory requirements

- Monitor for the use of analgesics as prescribed, especially in patients with risk factors for or history of abuse

- Provide written follow-up pain plan, including prescribed medications (See PAIN-I)

- Collaborate with patient’s pharmacist

- Ensure adequate access to prescribed medications, especially during transition between sites of care
  - Clarify which clinician will be prescribing patient’s ongoing analgesics

- Address system barriers
  - Analgesic cost/pharmacy benefit coverage
  - Availability of analgesics
  - Local laws/regulations
  - Obtain assistance from social services

- Instruct the patient on the importance of: (See PAIN-I)
  - Following documented pain plan
  - Scheduling and keeping outpatient appointments
  - Contacting clinician if pain worsens or adverse effects are inadequately controlled, including availability of after-hours assistance
  - Safely handling and disposing of analgesics

- Reevaluate patient-centered goals of care in the context of current disease and available therapies

- Maintain communication and coordinate care with pain specialist and relevant providers, especially during transition between sites of care

---

**GOALS OF TREATMENT**

Achieved → Continue routine follow-up

Not achieved →

- See Universal Screening and Assessment (PAIN-2)
- Consider pain management specialty consultation
- Consider interventional strategies (PAIN-M) or other treatments
- Consider palliative care consultation (See NCCN Guidelines for Palliative Care)

---

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
PAIN INTENSITY RATING (1 of 2)

- Pain intensity rating scales can be used as part of universal screening and comprehensive pain assessment. At minimum, patients should be asked about “current” pain, as well as "worst" pain, "usual" pain, and "least" pain in the past 24 hours. For each pain intensity rating, use one of the scales below.
- For comprehensive assessment, also include "worst pain in past week," "pain at rest," and "pain with movement." See Comprehensive Pain Assessment (PAIN-C) for more details.

Table 1: Numerical Rating Scale

Numerical rating scale:

- Verbal: “What number describes your pain from 0 (no pain) to 10 (worst pain you can imagine)’’
- Written: “Circle the number that describes your pain.”

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>

<td>Worst pain you can imagine</td>
</tr>
</tbody>
</table>

Categorical scale:

“What word best describes your pain?”

None (0), Mild (1–3), Moderate (4–6), or Severe (7–10)

Table 2: The Faces Pain Rating Scale - Revised

Instructions: “These faces show how much something can hurt. This face (point to the left-most face) shows no pain. Each face shows more and more pain (point to each face from left to right) up to this one (point to the right-most face)--it shows very much pain. Point to the face that shows how much you hurt (right now).”

PAIN INTENSITY RATING (2 of 2)

Pain assessment in the nonverbal patient

- The inability of patients to verbally communicate pain intensity because of cognitive or physiologic issues is a major barrier relating to pain assessment and management. Therefore, the American Society for Pain Management Nursing (www.aspmn.org) has developed a position statement and clinical practice recommendations clinicians may find useful in caring for such patients.
- In the absence of self-report, observation of behavior is a valid approach to pain assessment with the understanding that behaviors may also indicate other sources of distress, such as emotional stress or delirium, which may complicate assessment (See NCCN Guidelines for Distress Management). Potential causes and the context of the behavior must be considered when making pain treatment decisions.
- A multi-faceted approach is recommended that combines direct observation, family/caregiver input, and evaluation of response to pain medicines or nonpharmacologic interventions.
- For patients with advanced dementia, a comprehensive review of currently published tools, including those available at http://prc.coh.org/pain_assessment.asp, is recommended. These tools are in varying stages of development and validation and include, but are not limited to:
  - The Assessment of Discomfort in Dementia (ADD) protocol
  - Checklist of Nonverbal Pain Indicators (CNPI)
  - The Pain Assessment in Advanced Dementia (PAINAD) scale
- For patients who are intubated and/or are unconscious, pain assessment tools have been tested in specific situations and include, but are not limited to:
  - Behavioral Pain Scale (BPS); tested in adults and intensive care
  - Critical-Care Pain Observation Tool (CPOT); tested in adults and intensive care
- Clinicians are encouraged to monitor current research regarding new developments in strategies and tools for assessing pain in patients who have difficulty with self-reporting.

Cultural and linguistic assessment

- Health care providers should be aware of impact of cultural and linguistic diversity during universal screening and comprehensive pain assessment and respond with trained interpreters and culturally and linguistically appropriate educational materials.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
PROCEDURE-RELATED PAIN AND ANXIETY

- Anticipate and offer analgesic and anxiolytic therapy for procedures that are frequently accompanied by pain and/or anxiety.
- Events that are expected to cause discomfort to the patient such as diagnostic and therapeutic procedures (e.g., wound care, IV, arterial line, central line, injection, manipulation, bone marrow aspiration, lumbar puncture, skin biopsy, bone marrow biopsy, radiation procedure), as well as transportation/change in position for patients with incident pain, merit pretreatment with an analgesic intervention.

Providing information regarding all of the analgesic techniques described below prior to the procedure is ideal as it allows the patient and family/caregiver the time they may need to assimilate all of the information, ask questions, and master the techniques while reducing anticipatory anxiety.

- Intervention may be multimodal and potentially include one or more of the following as appropriate.
  - Analgesics
    - Supplemental doses of analgesics should be given in anticipation of procedure-related pain.
    - If procedure or transportation precludes continuation of IV PCA, give the prescribed IV bolus dose immediately before procedure/transport and administer a subcutaneous dose equivalent to 2-h basal infusion rate.
    - Additional analgesics and/or local anesthetics should be available immediately for further titration as needed.
  - Anxiolytics
    - Anxiolytics should be given preemptively when feasible.
  - Local anesthetics such as:
    - Topical local anesthetics creams (containing lidocaine, prilocaine, or tetracaine) applied to intact skin with sufficient time for effectiveness as per package insert.
    - Subcutaneous administration of lidocaine with a 27 gauge needle.
  - Administration of sedatives/analgesics/general anesthesia by trained personnel.
  - Integrative interventions for relief of pain and/or anxiety (See PAIN-J).
COMPREHENSIVE PAIN ASSESSMENT

- Patient's self report of pain is the standard of care. If the patient is unable to verbally report pain, an alternative method to obtain pain rating and response should be utilized (See PAIN-A 2 of 2).
- The goal of the comprehensive pain assessment is to find the cause of the pain and identify optimal therapies. Individualized treatment of the pain is based on the characteristics, cause of pain, the patient's clinical condition, and patient-centered goals of care.
- The etiology and pathophysiology of the pain should be investigated, including medical history (including psychosocial factors), physical exam, laboratory tests, and imaging studies.
  - Etiology factors may include direct involvement of cancer itself, cancer therapy (chemotherapy, RT, surgery) or procedures, and coincidental or noncancer pain (e.g., arthritis).
  - Pathophysiology factors may include nociceptive, neuropathic, visceral, effective, behavioral, and cognitive components.

Pain experience
- Location, referral pattern, radiation of pain(s)
- Intensity See Pain Intensity Rating (PAIN-A)
  - Last 24 hours and current pain
  - At rest and with movement
- Interference with activities See Impact of Pain Measurement (PAIN-C 3 of 3)
  - General activity, mood, walking ability, work ability, relationship with others, sleep, appetite, and enjoyment of life
- Timing: onset, duration, course, persistent, or intermittent
- Description or quality
  - Aching, stabbing, throbbing, or pressure often associated with somatic pain in skin, muscle, and bone
  - Gnawing, cramping, aching, or sharp pain often associated with visceral pain in organs or viscera
  - Burning, tingling, shooting, or electric/shocking pain often associated with neuropathic pain caused by nerve damage
- Aggravating and alleviating factors
- Other current symptoms; symptom clusters
- Current pain management plan, both pharmacologic and non-pharmacologic. If medications are used, determine:
  - What medication(s), prescription and/or over the counter?
  - Dose, route of administration, frequency?
  - Current prescriber?
  - Frequency?
  - Current prescriber?
  - Last 24 hours and current pain
  - At rest and with movement

Pain experience continued
- Response to current therapy
  - Pain relief
  - Patient adherence to medication plan
  - Medication adverse effects such as constipation, sedation, cognitive slowing, nausea, and others
- Breakthrough pain is episodic pain not controlled with existing pain regimen; see breakthrough pain on PAIN-E 3 of 10.
- Prior pain therapies
  - Reason for use, length of use, response, reasons for discontinuing, and adverse effects encountered
- Special issues relating to pain
  - Meaning and consequences of pain for patient and family/caregiver
  - Patient and family/caregiver knowledge and beliefs surrounding pain and pain medications
  - Cultural beliefs toward pain, pain expression, and treatment
  - Spiritual, religious considerations, and existential suffering
  - Patient goals and expectations regarding pain management
  - Assess for use of alternative or complementary therapies and screen for potential adverse interactions or effects

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
COMPREHENSIVE PAIN ASSESSMENT

- **Psychosocial Support** ([See PAIN-H](#))
  - Patient distress ([See NCCN Guidelines for Distress Management](#))
  - Family and other support; assess impact and burden on caregiver and recommend resources as appropriate
  - Psychiatric history including current or prior patient, family/caregiver, or household history of substance abuse
  - Risk factors for aberrant use or diversion of pain medication
    - Patient, environmental, and social factors as identified by a detailed patient evaluation\(^1\) and/or screening tools (eg, SOAPP-R\(^2\), ORT\(^3\))
  - Risk factors for undertreatment of pain
    - Being a pediatric, geriatric, minority, or female patient; communication barriers; history of substance abuse; neuropathic pain; and cultural factors
- **Medical history**
  - Oncologic treatment including current and prior chemotherapy, RT, and surgery
  - Other significant illnesses, conditions
  - Pre-existing chronic pain
- **Physical examination**
- **Laboratory and imaging studies to evaluate for disease progression**

---

### IMPACT OF PAIN MEASUREMENT

Mark the number that describes how much, in the past [week/24 hours], pain has interfered with your:

Version 2.2014, 04/11/14 © National Comprehensive Cancer Network, Inc. 2014, All rights reserved. The NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN®.
In general, cancer pain is treated with opioids as indicated on PAIN-3; these interventions are meant to complement management.

- Pain associated with inflammation:
  - Trial of NSAIDs or corticosteroids

- Bone pain without oncologic emergency:
  - NSAIDs and titrate analgesic to effect
  - Consider trial of bone-modifying agents (eg, bisphosphonates, denosumab)
  - Diffuse bone pain: Consider hormonal therapy or chemotherapy, corticosteroids, and/or systemic administration of radioisotopes
  - Local bone pain: Consider local RT, nerve block (eg, rib pain), vertebroplasty, or radiofrequency ablation
  - Consider physical medicine evaluation
    - See Specialty Consultations for Improved Pain Management (PAIN-L)
  - Consider orthopedic consultation for stabilization, if feasible
  - Consider referral to a pain specialist for interventional consultation. See Interventional Strategies (PAIN-M)

- Bowel obstruction
  - Evaluate etiology of bowel obstruction. If resulting from cancer, consider palliative surgery, radiation, and/or chemotherapy for symptomatic bowel obstruction.
  - Palliative management of bowel obstruction could include bowel rest, nasogastric suction (or percutaneous gastrostomy drainage), corticosteroids, and/or octreotide.

- Nerve pain
  - Nerve compression or inflammation:
    - Trial of corticosteroids
  - Neuropathic pain:
    - Trial of antidepressant, see PAIN-G
    - Trial of anticonvulsant, see PAIN-G
  - Consider trial of topical agent, see PAIN-G
  - For refractory pain, consider referral to a pain specialist and/or the use of interventional strategies. See Interventional Strategies (PAIN-M)

- Painful lesions that are likely to respond to antineoplastic therapies:
  - Consider trial of radiation, hormones, or chemotherapy

- For severe refractory pain in the imminently dying, see NCCN Guidelines for Palliative Care.
GENERAL PRINCIPLES
- The appropriate dose is the dose that relieves the patient’s pain throughout the dosing interval without causing unmanageable adverse effects.
- Titrate with caution in patients with risk factors such as decreased renal/hepatic function, chronic lung disease, upper airway compromise, sleep apnea, and poor performance status.
- Generally, oral route is most common; however, other routes (ie, IV, subcutaneous, rectal, transdermal, transmucosal) can be considered as indicated to maximize patient comfort. For intrathecal route administration, see PAIN-M.
- Calculate dosage increase based upon total opioid dose (around the clock/scheduled and as needed) taken in the previous 24 h.
- Increase both around-the-clock and as-needed doses. The rapidity of dose escalation should be related to the severity of the symptoms. See Management of Pain in Opioid-Tolerant Patients (PAIN-5).
- According to FDA guidelines, when higher doses of analgesic are needed, switch from preparations of opioid combined with other medications [such as aspirin or acetaminophen] to a pure opioid preparation to provide adequate analgesic to relieve pain while avoiding the toxicities of the non-opioid component of the combination (See PAIN-K).
- Steady state drug levels will be achieved when a stable drug dose has been routinely administered for a period equal to 5 times the drug elimination half life.
- If opioid dose reduction is desired or indicated, consider opioid dose reduction by 10%-25% with subsequent reevaluation and further dose adjustment.
- If patient is experiencing unmanageable adverse effects and pain is ≤3 (mild), consider downward dose titration by approximately 10%-25% and reevaluate. Close follow-up is required to make sure that the pain does not escalate, and that the patient does not develop symptoms of withdrawal.
- Consider opioid rotation if pain is inadequately controlled or there are persistent adverse effects from current therapy. Other indications for switching to a different opioid include: out-of-pocket costs, limitations based upon insurance formularies, etc.
- For breakthrough pain, see PAIN-E 3 of 10.
- Monitor for aberrant drug-taking behaviors. May include patient survey tool (eg, COMM1).

OPIOID PRINCIPLES, PRESCRIBING, TITRATION, MAINTENANCE, AND SAFETY (2 of 10)

OPIOIDS AND RISK EVALUATION AND MITIGATION STRATEGY (REMS)

Opioids are the principle analgesics for moderate to severe pain, yet opioids pose risks to patients and society. In the United States, poisoning is now the leading cause of death from injuries and 89% of poisonings are related to drugs. In 2008, of the 36,500 drug poisoning deaths, 14,800 (40%) involved opioid analgesics, compared to 5,100 cocaine-related deaths and 3,000 heroin-related deaths.

Responding to the “public health crisis of addiction, misuse, abuse, overdose, and death” the FDA is in the process of establishing REMS programs for all potent opioid products. Provider and patient education are the principal recommendations of proposed opioid REMS programs. Highlights include:

- Prescriber should evaluate each patient for risk factors associated with opioid misuse or abuse.
- Prescriber should educate each patient on safe use, storage, and disposal of opioid.
- Prescriber should routinely monitor patients for opioid misuse or abuse.

REMS programs are currently in place for:

- All transmucosal fentanyl products
- Long-acting, extended-release formulations
- hydromorphone
- morphine
- oxycodone
- oxymorphone
- tapentadol
- methadone tablets and solutions that are indicated for use as analgesics
- fentanyl or buprenorphine-containing transdermal delivery systems

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
PRINCIPLES OF MAINTENANCE OPIOID THERAPY

- For continuous pain, it is appropriate to give pain medication on a regular schedule with supplemental doses for breakthrough pain.
- Add extended-release or long-acting formulation to provide background analgesia for control of chronic persistent pain controlled on stable doses of short-acting opioids.
  - Initial range for converting to long-acting opioid would be 50% of the daily requirement.
- When possible, use the same opioid for short-acting and extended-release forms, excluding methadone due to its long duration of effect.
- Breakthrough pain (pain that fails to be controlled or “breaks through” a regimen of regularly scheduled opioid) may require additional doses of opioid for pain not relieved by regular schedule of long-acting (eg, extended-release) opioid. Breakthrough pain may be further evaluated into the following categories, which have direct impact on treatment:
  - Incident pain: pain associated with or incident to specific activities or events, potentially managed with short-acting opioid given in anticipation of those events
  - End-of-dose failure pain: pain recurring towards the end of dosing interval for regularly scheduled opioid, potentially managed by increasing the dose or frequency of regularly scheduled opioid
  - Uncontrolled persistent pain: pain routinely uncontrolled by existing regularly scheduled opioid, potentially managed by adjusting dose of regularly scheduled opioid
  - Increase dose of extended-release opioid if patient persistently needs doses of as-needed opioids or when dose of around-the-clock opioid fails to relieve pain at peak effect or at end of dose.
- Allow rescue doses of short-acting opioids of 10% to 20% of 24-h oral dose (mg) every 1 h as needed. Ongoing need for repeated rescue doses may indicate a need for adjustment of regularly scheduled opioid dose.
- Consider rapidly acting transmucosal fentanyl (various formulations and delivery systems are available) in opioid-tolerant patients for brief episodes of incident pain not attributed to inadequate dosing of around-the-clock opioid.
  - Data do not support a specific transmucosal fentanyl dose equianalgesic to other opioids or between different transmucosal formulations. Always initiate transmucosal fentanyl with lowest dose in chosen formulation and titrate to effect. (See specific transmucosal prescribing information for appropriate dosing intervals.)

</tbody>
</table>

<sup>2</sup>Codeine, morphine, or hydromorphone should be used with caution in patients with fluctuating renal function due to potential accumulation of renally cleared metabolites - monitor for neurologic adverse effects.

<sup>3</sup>Conversion factor listed for chronic dosing.

<sup>4</sup>In single-dose administration, 10 mg IV morphine is equivalent to approximately 100 mcg IV fentanyl but with chronic fentanyl administration, the ratio of 10 mg IV morphine is equivalent to approximately 250 mcg IV fentanyl. For transdermal fentanyl conversions, see PAIN-E 7 of 10.

<sup>5</sup>Long half-life, observe for drug accumulation and adverse effects, especially over first 4-5 days. In some individuals, steady state may not be reached for several days to 2 weeks. Methadone is typically dosed every 8-12 h.

<sup>6</sup>The oral conversion ratio of methadone varies. PRACTITIONERS ARE ADVISED TO CONSULT WITH A PAIN OR PALLIATIVE CARE SPECIALIST IF THEY ARE UNFAMILIAR WITH METHADONE PRESCRIBING. (See Special Notes Regarding Oral Methadone PAIN-E 9 of 10).

<sup>7</sup>Equivalence data not substantiated. Clinical experience suggests use as a mild, initial use opioid but effective dose may vary. Hydrocodone is only available commercially combined with acetaminophen (325 to 750 mg/tablet) or ibuprofen (200 mg/tablet).

<sup>8</sup>Codine has no analgesic effect unless it is metabolized into morphine, morphine-6-glucuronide by hepatic enzyme CYP2D6. Individuals with low CYP2D6 activity may receive no analgesic effect from codeine, but rapid metabolizers may experience toxicity from higher morphine production. Dosage must be monitored for safe limits as it may be available in combination with acetylsalicylic acid (ASA) or acetaminophen. Dose listed refers only to opioid portion.

<sup>9</sup>Shorter time generally refers to parenterally administered opioids (except for controlled-release products, which have some variability); longer time generally applies to oral dosing.

<sup>10</sup>Not recommended for cancer pain management because of CNS toxic metabolite - normeperidine.

<sup>11</sup>Mixed agonists-antagonists have limited usefulness in cancer pain. They should NOT be used in combination with opioid agonist drugs. Converting from an agonist to an agonist-antagonist could precipitate a withdrawal crisis in the opioid-dependent patient.

The FDA will be limiting the amount of acetaminophen in all prescription drug products to no more than 325 mg per dosage unit. Dosage must be monitored for safe limits of ASA or acetaminophen.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
Mixed-mechanism drugs:

- **Tramadol** is a weak mu-opioid agonist with some norepinephrine and serotonin reuptake inhibition used for mild to moderate pain. A maximum daily dose of 400 mg (100 mg four times daily) is recommended for adults with normal hepatic and renal function, and lower daily doses are recommended for older adults (≥75 y) and those with hepatic and/or renal dysfunction, to reduce the risk of seizures. Even at a maximum dose of 100 mg four times a day, tramadol is less potent than other opioid analgesics such as morphine.

- **Tapentadol** is a mu-opioid analgesic with norepinephrine reuptake inhibition for treatment of moderate to severe pain. Typical doses would start at 50-100 mg PO every 4 hours PRN, with a maximal daily dose of 500 mg per day (if using the extended release) or 600 mg per day (if using the immediate release only) due to lack of published data regarding higher doses. Some comparative data suggest tapentadol may have a lower incidence of GI adverse effects than oxycodone.

Partial agonists:

- **Transdermal buprenorphine**, a partial mu-agonist, has been approved for chronic pain. Although experience with this drug in the management of cancer pain is limited, anecdotal reports, a few small prospective uncontrolled studies, and at least one randomized trial support its use in cancer-related pain. Because buprenorphine is a partial mu-receptor agonist, it exhibits a ceiling to analgesic efficacy and may precipitate withdrawal symptoms if administered to individuals currently taking a high-dose opioid. FDA guidelines recommend limiting dose to 20 mcg per hour due to concern for QT prolongation. Conversion to buprenorphine from other opioids may be complex; consider a pain specialty consultation.

Non-opioid analgesics:

- **Ketamine** is a noncompetitive NMDA receptor antagonist that blocks glutamate. Low (subanesthetic) doses produce analgesia and modulate central sensitization, hyperalgesia, and opioid tolerance. There are only limited data regarding the use of ketamine as an adjuvant to opioids for management of cancer pain.

---

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
1. Determine the amount of current opioid(s) taken in a 24-h period that effectively control pain.
2. Calculate the equianalgesic dose of the new opioid. See Table 1 (PAIN-E 4 of 10).
3. If pain was effectively controlled, reduce the dose by 25%-50% to allow for incomplete cross-tolerance between different opioids. During the first 24 h, titrate liberally and rapidly to analgesic effect.
4. If previous dose was ineffective, may begin with 100% or 125% of equianalgesic dose.
5. Lastly, for oral opioids divide the total daily dose of new opioid needed by the number of doses per day to determine the individual dose (eg, 6 doses for regular PO morphine every 4 hrs; 2 doses for extended-release morphine every 12 h).
6. Data do not support a specific transmucosal fentanyl dose equianalgesic to other opioids or between different transmucosal formulations. Always initiate transmucosal fentanyl with lowest dose in chosen formulation and titrate to effect. (See specific transmucosal prescribing information for appropriate dosing intervals.)

Case example of converting IV morphine to IV hydromorphone

A patient is taking IV morphine at 8 mg/h and needs to be converted to IV hydromorphone.

1. Determine the total amount of current IV morphine in a 24-h period for this patient
   (8 mg/h x 24 hr = 192 mg/day)
   (Total amount of IV morphine this patient is taking is 192 mg/day)

2. From Table 1 on PAIN-E 4 of 10, calculate the equianalgesic dose of IV hydromorphone
   (10 mg IV morphine = 1.5 mg IV hydromorphone; therefore,
   192 mg/day IV morphine = 28.8 mg/day IV hydromorphone = 1.2 mg/h IV hydromorphone)

3. If patient was effectively controlled with IV morphine (192 mg/day), reduce the dose of hydromorphone by 25%-50%.
   (28.8 mg/day reduced by 25% = 21.6 mg/day IV hydromorphone = 0.9 mg/h IV hydromorphone)
   (28.8 mg/day reduced by 50% = 14.4 mg/day IV hydromorphone = 0.6 mg/h IV hydromorphone)
   If dose of IV morphine was ineffective in controlling pain, may begin with 100% of equianalgesic hydromorphone dose
   (28.8 mg/day IV hydromorphone = 1.2 mg/h IV hydromorphone)
   or increase that by 25%
   (36 mg/day IV hydromorphone = 1.5 mg/h IV hydromorphone)

Continued on next page
To convert or rotate from another opioid to transdermal fentanyl:
1. Determine the 24-h analgesic requirement of morphine.
2. From Table 2, select the mcg-per-hour dose of transdermal fentanyl based on the 24-h dose of morphine as listed. For fentanyl dosage requirements >100 mcg/h, multiple patches are used. See Table 1 (PAIN-E 4 of 10) for converting other opioids to morphine equivalent with subsequent conversion to transdermal fentanyl.

* Parenteral dosing such as IV (intravenous) or SubQ (subcutaneous)

NOTE: Due to patient variability the doses suggested in this guide are approximate and clinical judgement must be used to titrate to the desired response.

Special Notes Regarding Transdermal Fentanyl:
- Pain should be relatively well-controlled on a short-acting opioid prior to initiating the fentanyl patch. Patches are NOT recommended for unstable pain requiring frequent dose changes. Use fentanyl patch only in patients tolerant to opioid therapy.
- Fever, topical application of heat (such as heat from heat lamps, electric blankets, etc.), or extreme exertion may accelerate transdermal fentanyl absorption and are contraindications for transdermal fentanyl.
- An as-needed (PRN) dose of morphine or other short-acting opioid should be prescribed and will be needed, particularly during the first 8 to 24 hours.
- Once the levels have reached a steady state after at least 2-3 days, increase the patch dosage based on the average amount of stable daily as-needed (PRN) opioid required. Continue breakthrough medication once the patch dose is stabilized.
- When converting from continuous parenteral infusion fentanyl to transdermal fentanyl, a straight 1:1 ratio is appropriate, ie, the number of mcg of parenteral fentanyl per hour should be approximately equal to the number of mcg of transdermal fentanyl per hour. In some patients, additional dose titration of the fentanyl patch may be necessary.
- The fentanyl patch analgesic duration is usually 72 hours, but some patients require fentanyl patch replacement every 48 hours.

---

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
CONVERT OR ROTATE FROM ANOTHER OPIOID TO TRANSDERMAL FENTANYL (continued)

Example of opioid using Table 2 directly:
Case example of converting oral morphine to transdermal fentanyl patch
A patient is taking 30 mg of sustained-release oral morphine every 12 h and needs to be converted to transdermal fentanyl patch.

1. Calculate the total amount of current oral morphine in a 24-h period.
   (oral morphine 30 mg x 2 = 60 mg/day oral morphine)

2. Using Table 2, select the mcg-per-hour dose of transdermal fentanyl
   (60 mg/day oral morphine is approximately 25 mcg/h transdermal fentanyl patch)

Example of opioid not listed in Table 2:
Case example of converting oral oxymorphone to transdermal fentanyl patch
A patient is taking 10 mg of sustained-release oral oxymorphone every 12 h and needs to be converted to transdermal fentanyl patch.

1. Calculate the total amount of current oral oxymorphone in a 24-h period
   (oral oxymorphone 10 mg x 2 = 20 mg/day oral oxymorphone)

2. From Table 1 on PAIN-E 4 of 10, convert to the equianalgesic dose of oral morphine
   (Based on Table 1, 10 mg oral oxymorphone = 30 mg oral morphine; therefore,
   20 mg/day oral oxymorphone x 3 = total daily dose oral morphine of 60 mg/day)

3. Using Table 2 on PAIN-E 7 of 10, select the mcg-per-hour dose of transdermal fentanyl
   (60 mg/day oral morphine is approximately 25 mcg/h transdermal fentanyl patch)
Special Notes Regarding Oral Methadone:

- Due to the unique nature of methadone with a long and variable half-life, caution should be used and frequent and careful evaluation should be performed.
- The conversion ratio varies with the amount of morphine (or other opioid) a patient has been using chronically. The higher the dose of morphine, the more potent methadone is. PRACTITIONERS ARE ADVISED TO CONSULT WITH A PAIN OR PALLIATIVE CARE SPECIALIST IF THEY ARE UNFAMILIAR WITH METHADONE PRESCRIBING or if individual patient considerations necessitate very rapid switching to or from methadone.
- To a significantly greater extent than with other opioids, methadone has been associated with many drug-drug interactions. The potential for such interactions must be investigated in each patient before initiating methadone.
- Methadone is commercially available in 5 mg and 10 mg tablets and 1 mg/mL, 2 mg/mL, and 10 mg/mL oral solution.
- Methadone may be titrated up every 5-7 days, usually by 5 mg/dose. If more rapid titration is desired, consult with pain or palliative care specialist.
- Methadone is typically given at a regular schedule with additional doses of a short-acting opioid given as needed.
- Because methadone is associated with QTc prolongation, a baseline and follow-up electrocardiogram (ECG) is recommended for methadone doses >100 mg/day and for patients with cardiac disease, or when methadone is used in patients taking other medications also known to prolong QTc (including tricyclic anti-depressants), if consistent with patient’s goals of care. QTc ≥450 may indicate need to reduce or discontinue methadone dose.
- These conversion ratios should NOT be used in converting from methadone to other opioids. After methadone is discontinued, it will take several days for it to be cleared due to a long elimination half-life; therefore, the amount of other opioid needed for an equivalent effect will appear to change as the residual methadone is cleared. On the first day of conversion (while there is still significant methadone present), a conservative conversion ratio for oral methadone to oral morphine of 1:1 may be used and supplemented with additional short-acting opioid, as needed. As methadone is cleared, morphine (or other opioid) doses will likely require frequent adjustment (every day or two) towards the higher conversion ratios listed for morphine-to-methadone conversion.
- It may be necessary to educate patients and families about analgesic utility of methadone. Some may only be familiar with methadone use for maintenance of addiction and be unaware of its utility as a potent opioid analgesic.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

See Convert from Oral Morphine to Oral Methadone (PAIN-E 10 of 10)
CONVERT FROM ORAL MORPHINE TO ORAL METHADONE

1. Calculate the total daily oral morphine dose (or morphine-equivalent dose) the patient is using.

2. Based on the oral morphine dose, use Table 3 below to determine the appropriate dose conversion ratio and calculate the oral methadone dose.

3. Reduce the calculated equianalgesic dose of oral methadone by 25%-50% to account for incomplete cross-tolerance, dosing ratio variability, and patient variability.

4. Divide the total daily oral methadone dose into 3 or 4 daily doses.

Case example of converting oral morphine to oral methadone

A patient is taking oral morphine at 30 mg every 4 h and needs to be converted to oral methadone.

1. Calculate the total amount of current oral morphine in a 24-h period for this patient
   
   \[(30 \text{ mg} \times 6 = 180 \text{ mg/day})\]
   
   (Total amount of oral morphine this patient is taking is 180 mg/day)

2. From Table 3 above, calculate equianalgesic dose of oral methadone
   
   (For 180 mg/day of oral morphine : oral methadone, the dose conversion ratio is 8:1; therefore,
   
   \[180 \text{ mg/day morphine = 22.5 mg/day methadone}\])

3. Reduce the calculated equianalgesic dose of oral methadone by 25% to 50% to account for incomplete cross-tolerance, dosing ratio variability, and patient variability.

   (for example, 22.5 mg/day oral methadone reduced by 25% = 16.875 mg/day oral methadone
   
   equal to approximately 15 mg/day oral methadone)

4. Divide the total daily oral methadone dose into 3 daily doses.

   (for example, reduced dose of 15 mg/day oral methadone divided by 3 daily doses = 5 mg oral methadone every 8 h)

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
Principles of Management of Opioid Adverse Effects

- Adverse effects to opioids are common, should be anticipated, and should be managed aggressively.
- Patient and family/caregiver education is essential for successful anticipation and management of pain and opioid adverse effects.
- Recognize that pain is rarely treated in isolation in cancer and adverse effects also may be from other treatments or cancer itself.
- Opioid adverse effects generally improve over time, except with constipation. Maximize non-opioid and nonpharmacologic interventions to limit opioid dose and treat adverse effects. If adverse effects persist, consider opioid rotation.
- Multisystem assessment is necessary.
- Information from patient and family/caregiver about adverse effects is essential for appropriate opioid dose adjustment and treatment of adverse effects.

Constipation

- Preventive measures
  - Prophylactic medications
    - Stimulant laxative ± stool softener (eg, senna ± docusate, 2 tablets every morning; maximum 8-12 tablets per day).
    - Polyethylene glycol (1 capful/8 oz water PO two times a day)
    - Increase dose of laxative when increasing dose of opioids
  - Maintain adequate fluid intake
  - While maintaining adequate dietary fiber intake is recommended, supplemental medicinal fiber such as psyllium (eg, Metamucil) is unlikely to control opioid-induced constipation and is not recommended.
  - Stool softener (docusate) alone may not provide benefit in well-hydrated patients.
  - Exercise, if feasible
- If constipation develops
  - Assess for cause and severity of constipation
  - Rule out obstruction
  - Titrate stool softener/laxatives as needed with goal of one non-forced bowel movement every 1-2 d
  - Consider adjuvant analgesic to allow reduction of the opioid dose
- If constipation persists
  - Reassess for the cause and severity of constipation, rule out bowel obstruction

- Check for impaction
- Consider adding another agent, such as magnesium hydroxide, 30-60 mL daily; bisacodyl, 2-3 tablets PO daily; 1 rectal suppository daily; lactulose, 30-60 mL daily; sorbitol, 30 mL every 2 h x 3, then as needed; magnesium citrate, 8 oz PO daily; or polyethylene glycol (1 capful/8 oz water PO two times a day)
- Consider use of a prokinetic agent (eg, metoclopramide, 10-15 mg PO 4 times a day; consider limiting chronic use to maximum 3 mo, due to concern for neurologic complications [tardive dyskinesia], especially in frail, elderly patients)
- When response to laxative therapy has not been sufficient for opioid-induced constipation in patients with advanced illness, consider methylnaltrexone, 0.15 mg/kg subcutaneously, maximum one dose per day
- For intractable chronic constipation, consider opioid rotation to fentanyl or methadone
- Consider neuraxial analgesics, neuroablative techniques, or other interventions to decrease pain, alleviate constipation, and/or reduce opioid dose

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
**Nausea**

- Preventive measures
  - Ensure that patient is having bowel movements consistently.
  - For patients with a prior history of opioid-induced nausea, prophylactic treatment with antiemetic agents (see below) is highly recommended.
  - If nausea develops
    - Assess for other causes of nausea (eg, central nervous system [CNS] pathology, chemotherapy, RT, hypercalcemia).
    - Consider prochlorperazine, 10 mg PO every 6 h as needed; or metoclopramide, 10-15 mg PO 4 times daily as needed; or haloperidol, 0.5-1 mg PO every 6-8 h. Chronic use of any of these agents may be associated with development of tardive dyskinesia, especially in frail, elderly patients.
    - If nausea persists despite as-needed regimen, administer antiemetics around the clock for 1 wk, then change as needed.
    - Consider adding a serotonin antagonist (eg, ondansetron, 8 mg PO 3 times a day; granisetron, 2 mg PO daily). Use with caution as constipation is an adverse effect.
    - Dexamethasone can be considered.
    - Consider olanzapine, 2.5-5 mg, especially with bowel obstruction.
  - Opioid-induced nausea may resolve with continued exposure; if nausea persists for more than 1 wk
    - Reassess cause and severity of nausea.
    - Consider opioid rotation.
  - If nausea persists after a trial of several opioids and above measures
    - Reassess cause and severity of nausea.
    - Consider neuraxial analgesics, neuroablative techniques, and other interventions to potentially reduce opioid dose.

**Pruritus**

- If pruritus develops
  - Assess for other causes (other medications, etc.)
  - If pruritus is associated with rash or hives, consider true allergy and reconsider selection of opioid therapy.
  - Consider antihistamines such as diphenhydramine, 25-50 mg IV or PO every 6 h; or promethazone, 12.5-25 mg PO every 6 h
  - If pruritus persists
    - Consider changing to another opioid if symptomatic management has failed.
    - Consider adding to analgesic regimen: small doses of mixed agonist-antagonist, nalbuphine, 0.5-1 mg IV every 6 h as needed
    - Consider continuous infusion of naloxone, 0.25 mcg/kg/h and titrate up to 1 mcg/kg/h for relief of pruritus without decreasing effectiveness of the analgesic.

**Delirium**

- Assess for other causes of delirium (eg, hypercalcemia, CNS, metastases, other psychoactive medications)
- If other possible causes of delirium are excluded, consider changing the opioid
- Consider nonopioid analgesic to allow reduction of the opioid dose
- Consider initial titration with haloperidol, 0.5-2 mg PO or IV every 4-6 h; or olanzapine, 2.5-5 mg PO or sublingual every 6-8 h; or risperidone, 0.25-0.5 mg 1-2 times per day. With prolonged administration of these agents, it may be necessary to decrease dose due to long elimination half-life.
- For further information about delirium, see NCCN Guidelines for Palliative Care.

Continued on next page
Motor and Cognitive Impairment

- Studies have shown that stable doses of opioids (>2 wk) are not likely to interfere with psychomotor and cognitive function, but these functions should be monitored during analgesic administration and titration.

Respiratory Depression

- Patients with limited cardiopulmonary reserve are more susceptible.
- Hypercarbia occurs before hypoxia.
- If respiratory problems or opioid-induced sedation occurs, consider naloxone administration but use reversing agents cautiously.
  - Dilute one ampule of naloxone (0.4 mg/1 mL) into 9 mL of normal saline for a total volume of 10 mL. Give 1-2 mL (0.04-0.08 mg) every 30-60 seconds until improvement in symptoms is noted.
  - Be prepared to repeat this process (the half-life of opioids is generally longer than that of the naloxone [plasma half-life is 30-80 minutes]).
  - If the patient is not responsive within 10 minutes and total naloxone dose of 1 mg, consider another reason for the change in neurologic status.
- If reversing an opioid with a long half-life such as methadone or for persistent opioid-induced sedation, consider naloxone infusion.
- Closely monitor for the recurrence of pain as opioid is metabolized during reversal, which may require a cautious administration of an additional opioid.

Sedation

- If significant or unexpected sedation develops and persists for more than 2-3 d after initiating or a significant upward titration of an opioid
  - Assess for other causes of sedation (eg, CNS pathology, other sedating medications, hypercalcemia, dehydration, sepsis, hypoxia)
  - Consider a lower dose of opioid given more frequently to decrease peak concentrations
  - Decrease the dose of opioid if pain control can be maintained at a lower dose
  - Consider opioid rotation
  - Consider nonopioid analgesic to allow reduction of the opioid dose
  - Consider the addition of caffeine, 100-200 mg PO every 6 h; or methylphenidate, 5-10 mg 1-3 times per day; or dextroamphetamine, 5-10 mg PO 1-3 times per day; or modafinil, 100-200 mg per day.
  - When using CNS stimulants for sedation, limit dosing to morning and early afternoon to avoid insomnia at night.
- If sedation persists despite several changes of opioids and the above measures
  - Reassess cause and severity of sedation
  - Consider neuraxial analgesics, neuroablative techniques, and other interventions to potentially reduce opioid dose
  - If the patient has had marked sleep deprivation related to poor pain control, adjustments of analgesics to improve pain control may result in "catch up" sleep lasting 2-3 days. Therefore, extreme fatigue can result in somnolence that may be difficult to differentiate from opioid-induced sedation. If related to fatigue, patients generally can be fully aroused, although this may require some effort.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
Principles of Adjuvant Analgesic Use

- Antidepressants and anticonvulsants are first-line adjuvant analgesics for the treatment of cancer-related neuropathic pain.
- These drugs can be helpful for patients whose pain is only partially responsive to opioids.
- The use of adjuvant analgesics in the cancer population is often based on guidelines or experience derived from data for the treatment of pain not caused by cancer (non-malignant pain).
- Effective use is predicated on an assessment that clarifies the nature of the pain as most adjuvant analgesics are more likely to be effective in management of neuropathic pain.
- As with opioids, response to adjuvant analgesics may vary according to the type/cause of neuropathic pain and the individual patient.
- Drug selection may be influenced by other symptoms and comorbidities. For example, a sedating drug may be useful in a patient in whom insomnia is a problem.
- Patient education should emphasize the trial and error nature of the treatment so patients do not get discouraged.
- Doses should be increased until the analgesic effect is achieved, adverse effects become unmanageable, or the conventional maximal dose is reached.

See Examples of Adjuvant Analgesics Use for Neuropathic Pain (PAIN-G 2 of 2)
ADJUVANT ANALGESICS FOR NEUROPATHIC PAIN (2 of 2)
(ANTIDEPRESSANTS, ANTICONVULSANTS, TOPICAL AGENTS, AND CORTICOSTEROIDS)

Examples of Adjuvant Analgesics Use

- Extrapolated from non-cancer neuropathic pain management
- Both antidepressants and anticonvulsants are frequently used as an adjuvant analgesic in combination with an opioid to treat neuropathic components of pain.

- **Antidepressants**: Analgesic effectiveness is not dependent on its antidepressant activity. Effective analgesic dose 1) may be lower than that required to treat depression; and 2) the onset of analgesic relief may occur earlier than anti-depressive effects.

- **Tricyclic antidepressants** (eg, amitriptyline, imipramine, nortriptyline, desipramine)
  - Start with low dose and increase every 3-5 days if tolerated. (eg, nortriptyline and desipramine starting dose 10-25 mg nightly increase to 50-150 mg nightly). The tertiary amines (amitriptyline, imipramine) may be more efficacious but secondary amines (nortriptyline, desipramine) are better tolerated. Anticholinergic adverse effects such as sedation, dryness of mouth, and urinary hesitancy are more likely to occur with amitriptyline and imipramine.

- **Other examples**:
  - Duloxetine- Starting dose 30-60 mg daily, increase to 60-120 mg daily
  - Venlafaxine- Starting dose 50-75 mg daily, increase to 75-225 mg daily

Note: Some SSRI, SNRI antidepressants may inhibit the conversion of tamoxifen to its active metabolite, thereby decreasing the effectiveness of tamoxifen - see Discussion.

- **Anticonvulsants**: Frequently used as an adjuvant analgesic in combination with an opioid for the neuropathic component of the pain.

  - **Anticonvulsants examples**:
    - gabapentin- Starting dose 100-300 mg nightly, increase to 900-3600 mg daily in divided doses 2 to 3 times a day. Dose increments of 50%-100% every 3 days. Slower titration for the elderly or medically frail. Dose adjustment required for those with renal insufficiency.
    - pregabalin- Starting dose 50 mg three times a day, increase to 100 mg 3 times a day. Slower titration for the elderly or medically frail. Dose adjustment required for those with renal insufficiency. Pregabalin more efficiently absorbed through the GI tract than gabapentin. May increase further to a maximum dose of 600 mg in divided doses 2 to 3 times a day.
    - Consider other anticonvulsant agents, many of which have been shown to have efficacy in non-cancer neuropathic pain.

- **Topical agents**: Act locally and may be used as an adjuvant analgesic in combination with an opioid, antidepressant, and/or an anticonvulsant.

  - **Topical agent examples**:
    - lidocaine patch- 5% - Apply daily to the painful site. Minimal systemic absorption.
    - Consider NSAID- diclofenac gel 1%, four times daily; or diclofenac patch 180 mg, one patch daily or one patch twice daily

- **Corticosteroids**: Long half-life of these drugs allows for once daily dosing. Useful in the acute management of a pain crisis when neural structures or bones are involved. Long-term adverse effects significant.

**Note**: All recommendations are category 2A unless otherwise indicated.
**Clinical Trials**: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
PSYCHOSOCIAL SUPPORT

- Due to the complexity of cancer-related pain and associated symptoms, health care providers should anticipate patients’ and families’ need for support and education in management strategies.
- Assessing each patients’ need for psychosocial support is an essential component of a comprehensive pain assessment (See PAIN-C).

Support

- Inform patient and family/caregiver that emotional reactions to pain are normal and are evaluated and treated as part of pain treatment.
- Provide emotional support to patient and family/caregiver that acknowledges that the pain is a problem to be addressed.
- Assist in accessing treatment as needed.
- State that you will work together with the patient and family/caregiver as part of the team to address the pain problem.
- Describe the plan of action to be taken and when results can be expected.
- Express your commitment to being available to help with pain management.
- Inform patient and family/caregiver that there is ALWAYS something else that can be done to try to adequately manage pain and other noxious symptoms.
- Assess impact upon family and significant others; provide education and support as indicated.
- Verbally repeat your concern and the plan of action to be taken.

Skills training

- Teach coping skills (to be used in conjunction with and not in lieu of appropriate analgesia) to provide pain relief, enhance a sense of personal control, and refocus energy on optimizing quality of life.
  - Coping skills for acute pain include Lamaze-type breathing exercises, distraction techniques
  - Coping skills for chronic pain (not pain emergency) include all of the above plus relaxation techniques, guided imagery, graded task assignments, and hypnosis to maximize function
  - Training to encourage assertiveness to maximize comfort
- Educate patient and family/caregiver that in pain management a team effort is necessary to comprehensively assess and treat the impact of pain. Members of the team may include: oncologist, nurse, pain specialist, palliative care clinician, physiatrist, neurologist, psychologist, social worker, psychiatrist, physical therapist, and spiritual counselor.

See Patient and Family/Caregiver Education (PAIN-I)
PATIENT AND FAMILY/CAREGIVER EDUCATION (1 of 2)

- To assess for patient and family/caregiver educational needs regarding pain treatment, the health care team should:
  - Assess for meaning and consequences of pain for patient and family/caregiver.
  - Assess for literacy to ensure understanding of education.
  - Assess existing knowledge of pain and pain treatment to aid in developing appropriate patient and family/caregiver education plan.1,2

- Messages to be conveyed to patient and family/caregiver regarding management of pain
  - Relief of pain is medically important and there is no medical benefit to suffering with pain.
  - Pain can usually be well-controlled with pain medications. For persistent pain, taking an analgesic on a regular schedule will improve pain control.
  - Patients with pain often have other symptoms (e.g., constipation, nausea, fatigue, insomnia, depression) that need to be controlled; management of these other symptoms may facilitate control of pain.

- Messages to be conveyed to patient and family/caregiver regarding opioid analgesics
  - Morphine and morphine-like medications are principal medications used to relieve severe pain.
    - If you take these medications now, they will still work later.
    - If these medications do not work, many other options are available.
  - When these medications are used to treat cancer pain, addiction is rarely a problem unless addiction issues existed before the cancer pain.
    - Patients with a history of prescription, illicit drug, or alcohol dependence/substance abuse may be at increased risk for prescribed medication misuse/abuse (see PAIN-L).
    - Patients with history of opioid use/abuse may also have increased tolerance, which may require higher doses for optimal pain control (see PAIN-L).
  - These medications are controlled substances and must be used with caution:
    - These medications should not be mixed with alcohol or illicit substances.
    - Potent analgesics should be taken only as prescribed and by the person for whom the medication is prescribed; advise patients not to self-adjust dosage or frequency unless discussed with health care provider; and advise patients to contact health care provider if the pain management regimen is not controlling their pain.
    - Analgesics must be in a secured location, preferably in a locked box and not in a medicine cabinet.
    - Unused or unneeded medications (especially opioid analgesics) must be properly disposed of:
      - Per the FDA, unless a take-back drug program is immediately available, the recommendation is to flush excess opioids down sink or toilet.
      - Read the product-specific disposal information included with the extended-release/long-acting opioid product.
    - Provide information pertaining to local regulations regarding the operation of machinery or motor vehicles while taking potentially sedating medication and advise patient and family/caregiver accordingly and provide appropriate medical counseling.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

Continued on next page
PATIENT AND FAMILY/CAREGIVER EDUCATION (2 of 2)

- Communication with the health care provider is critical for the patient and family/caregiver to assist in meeting goals of care.
  - Explain that health care providers cannot discern the patient’s pain level, and that describing pain is not viewed as “complaining,” but rather is an essential source of information to enable the health care provider to adjust treatment.
  - Explain that health care providers want to know about any problems the patient believes the pain medications may be causing, as there are probably ways to alleviate these issues.
  - Tell the patient to let the health care providers know about difficulty obtaining medication or concerns about taking medication. Explain that providers have dealt with such issues before and that they can help.
  - Expect optimal management for pain and adverse effects. Inform the patient of the right to expect pain management as part of overall care.

- The following must be reviewed with each patient and family/caregiver and provided in written form, which is dated:
  - A list of each medication prescribed, a description of what each medication is for, and instructions as to how and when to take each one
  - A plan for obtaining refilled prescriptions, especially potent opioids, because schedule II narcotics cannot be ordered by telephone
  - A list of potential adverse effects of these medications and what to do if they occur
    - List may be provided by clinician and/or pharmacy
  - A list of all medications to be discontinued
  - A list of telephone numbers to reach an appropriate health care provider and specific instructions to call regarding:
    - Any problems in getting the prescriptions or taking the medication
    - New pain, change in pain, or pain not relieved with medication
    - Nausea and vomiting that prevents eating for 1 day
    - Problems with bowel movements, including no bowel movements for 3 days
    - Difficulty arousing the patient from sleep easily during the daytime
    - Confusion
  - A plan for follow-up visits and/or phone calls, including availability of after-hours assistance
  - A plan for proper storage and disposal (see PAIN-I 1 of 2)

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
INTEGRATIVE INTERVENTIONS

Consider integrative interventions in conjunction with pharmacologic interventions as needed. Integrative interventions may be especially important in vulnerable populations (eg, frail, elderly, pediatric) in whom standard pharmacologic interventions may be less tolerated or based on patient preference. The utility of integrative interventions underscores the necessity for pain management to be carried out with a team approach that contains a wide range of treatment options.

Pain likely to be relieved or function improved with physical, cognitive, or interventional modalities:

• Physical modalities
  ➤ Bed, bath, and walking supports
  ➤ Positioning instruction
  ➤ Physical therapy
  ➤ Energy conservation, pacing of activities
  ➤ Massage
  ➤ Heat and/or ice
  ➤ Transcutaneous electrical nerve stimulation (TENS)
  ➤ Acupuncture or acupressure
  ➤ Ultrasonic stimulation

• Cognitive modalities
  ➤ Imagery/hypnosis
  ➤ Distraction training
  ➤ Relaxation training
  ➤ Active coping training
  ➤ Graded task assignments, setting goals, pacing, and prioritizing
  ➤ Cognitive behavioral training

• Spiritual care (See NCCN Guidelines for Distress Management)

• See Intervenational Strategies (PAIN-M)
NON-OPIOID ANALGESIC (NONSTEROIDAL ANTI-INFLAMMATORY DRUGS [NSAIDS] AND ACETAMINOPHEN) PRESCRIBING (1 of 2)

Acetaminophen

- Acetaminophen, 650 mg every 4 h or 1 g every 6 h (daily maximum 4 g/d) in adult patients with normal liver function. For chronic administration, consider limiting the maximum daily dose to 3 g/d or less due to concerns for hepatic toxicity.
- Due to concerns with liver toxicity, acetaminophen should be used with caution or not used at all with combination opioid-acetaminophen products to prevent excess acetaminophen dosing.
- See the FDA website [www.fda.gov](http://www.fda.gov) for the latest information on acetaminophen adverse effects and dosing.

NSAIDs

- Use NSAIDs with caution, especially for chronic use, as many oncology patients may be at high risk for renal, GI (upper GI surgery, RT), or cardiac toxicities; thrombocytopenia; or bleeding disorder.
- Note that the potential adverse effects of chemotherapy (especially angiogenesis inhibitors), such as hematologic (thrombocytopenia, coagulopathy), renal, hepatic, and cardiovascular toxicities, can be increased by the concomitant prescription of NSAIDs.
- For some patients opioid analgesics may be a safe and effective alternative analgesic to NSAIDs.
- Use any NSAID that the patient has found to be effective and well tolerated in the past; otherwise, consider ibuprofen to the maximal dose.
  - Ibuprofen, 400 mg four times a day (daily maximum = 3200 mg)
  - If needed, consider short-term use of ketorolac, 15-30 mg IV every 6 h for a maximum of 5 days
  - Compounds that do not inhibit platelet aggregation:
    - Nonacetylated salicylate
    - Choline + magnesium salicylate combinations, 1.5-4.5 g/d in three divided doses
    - Salsalate, 2-3 g/d in two or three divided doses
    - Selective COX-2 inhibitor

See NSAIDs and toxicities on next page
NON-OPIOID ANALGESIC (NONSTEROIDAL ANTI-INFLAMMATORY DRUGS [NSAIDS] AND ACETAMINOPHEN) PRESCRIBING (2 of 2)

NSAIDs and toxicities

Renal toxicities
- Patients at high risk: age >60 y, compromised fluid status, multiple myeloma, diabetes, interstitial nephritis, papillary necrosis, and concomitant administration of other nephrotoxic drugs (including cyclosporine, cisplatin) and renally excreted chemotherapy
- Treatment: reevaluate NSAID use if renal function deteriorates or if hypertension develops or worsens

GI toxicities
- Patients at high risk: age >60 y, history of peptic ulcer disease or significant alcohol use (3 or more alcoholic beverages/day), major organ dysfunction including hepatic dysfunction, high-dose NSAIDs given for long periods, concomitant steroid use
- Treatment:
  - If patient develops gastric upset or nausea, consider discontinuing NSAID or changing to selective COX-2 inhibitor. COX-2 inhibitors are associated with lower incidence of GI adverse effects and do not inhibit platelet aggregation; however, they have not been demonstrated to have reduced renal adverse effects.
  - As prophylaxis for NSAID peptic ulceration, consider adding misoprostol or proton pump inhibitors. If patient develops GI peptic ulcer or GI hemorrhage, discontinue NSAID.
  - Discontinue NSAID if liver function studies increase 1.5 times the upper limit of normal.

Cardiac toxicities
- Patients at high risk: history of cardiovascular disease or at risk for cardiovascular disease or complications.\(^1\) NSAIDs taken with prescribed anticoagulants, such as warfarin or heparin, may significantly increase the risk of bleeding complications.
- Treatment: discontinue NSAID if congestive heart failure or hypertension develops or worsens. Naproxen and ibuprofen are preferred NSAIDs for individuals at high risk for cardiac toxicities.

Monitoring for NSAID toxicities
- Baseline blood pressure, BUN, creatinine, liver function studies [alkaline phosphatase, LDH, SGOT, SGPT], CBC, and fecal occult blood
- Repeat every 3 mo to ensure lack of toxicity

Further NSAID considerations
- If two NSAIDs are tried in succession without efficacy, use another approach to analgesia.
- If NSAIDs are effective but treatment is limited by toxicities that are not deemed serious, consider trial of another NSAID.
- When systemic administration is not feasible, consider topical NSAID preparations in place of oral NSAIDs.
- Toxicity of anti-cancer treatment may increase the risk profile of anti-inflammatory treatment.
- The use of concomitant NSAID with prophylactic aspirin may reduce the effectiveness of aspirin. Therefore, it is recommended to either avoid use or take separately to avoid this possibility.

SPECIALTY CONSULTATIONS FOR IMPROVED PAIN MANAGEMENT

- Major indication for referral is:
  - Pain likely to be relieved or function improved through consultation delivered by a specialty service provider as suggested below.
  - Note that the specific provider of these services may vary in different treatment settings.

- Pain and palliative care specialty consultation
  - Consider interventional strategies (See PAIN-M)
  - Management of symptoms refractory to initial treatment
  - Management of sleep disturbances
  - Diagnosis and treatment of underlying condition
  - Consider oral or IV ketamine for pain resistant to other analgesics
  - Consider palliative sedation for intractable pain
  - Adjustment of drugs and doses beyond the expertise of the primary team/oncologist
  - Management of complicated psychosocial issues, including aberrant drug behavior
  - Clarity of goals of care, especially regarding pain and medication side effects

- Psychiatric consultation
  - Pharmacologic management and psychotherapy

- Depression/distress consultation
  - See NCCN Guidelines for Distress Management

- Psychology consultation
  - Cognitive modalities
    - Imagery/hypnosis
    - Distraction training
    - Relaxation training
    - Active coping training
    - Graded task assignments, setting goals, pacing, and prioritizing
    - Cognitive behavioral training

- Social work consultation
  - Caregiver burden and support needs
  - Recommend use of community care resources

- Substance abuse consultation if questions/concerns about medication misuse or diversion
  - Evaluate for substance use disorder
  - Assist with establishing treatment agreements, limit setting, single provider/pharmacy as needed
  - Communicate regarding need to accomplish pain relief, but avoid misuse/diversion

- Spiritual care consultation
  - Determine importance to patient and family/caregiver and current availability of support
  - Manage spiritual, existential concerns

- Physical/occupational therapy, rehabilitation/mobility specialty consultation
  - Physical modalities
    - Bed, bath, and walking supports
    - Positioning instruction
    - Energy conservation, pacing of activities
    - Massage
    - Heat and/or ice
    - TENS
    - Acupuncture or acupressure
    - Ultrasonic stimulation
  - Lymphedema management

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
INTERVENTIONAL STRATEGIES

Interventional consultation

- Major indications for referral:
  - Pain likely to be relieved with nerve block (e.g., pancreas/upper abdomen with celiac plexus block, lower abdomen with superior hypogastric plexus block, intercostal nerve, peripheral/plexus nerve)
  - Failure to achieve adequate analgesia and/or the presence of intolerable adverse effects (may be handled with intraspinal agents, blocks, spinal cord stimulation, or destructive neurosurgical procedures)

- Commonly used interventional procedures:
  - Regional infusions (requires infusion pump)
    - Epidural: easy to place, requires large volumes and an externalized catheter; for infusions of opioids, local anesthetics, and clonidine, useful for acute postoperative pain; use beyond several days to a few weeks is limited by concerns for catheter displacement and infection
    - Intrathecal: easy to internalize to implanted pump; for infusions of opioids, local anesthetics, clonidine, and ziconotide; implanted infusion pumps may be costly, refills require technical expertise
    - Regional plexus: for infusions of local anesthetics, to anesthetize single extremity; use beyond several days to a few weeks is limited by concerns for catheter displacement and infection
  - Percutaneous vertebroplasty/kyphoplasty
  - Neurodestructive procedures for well-localized pain syndromes (spinal analgesics are used more frequently)
    - Head and neck: peripheral neurolysis generally associated with sensory and/or motor deficit
    - Upper extremity: brachial plexus neurolysis
    - Thoracic wall: epidural or intrathecal, intercostal, or dorsal root ganglion neurolysis
    - Upper abdominal pain (visceral): celiac plexus block, thoracic splanchnicectomy
    - Midline pelvic pain: superior hypogastric plexus block
    - Rectal pain: intrathecal neurolysis, midline myelotomy, superior hypogastric plexus block, or ganglion impar block
    - Unilateral pain syndromes: cordotomy
    - Consider intrathecal L/S phenol block
  - Neurostimulation procedures for cancer-related symptoms
    - (i.e., peripheral neuropathy, neuralgias, complex regional pain syndrome)
  - Radiofrequency ablation for bone lesions

- If interventional approaches are appropriate
  - Evaluate which pain site can be relieved
  - Verify that interventional technique will provide sufficient benefit

- If interventional approaches are not appropriate
  - Reassess therapeutic plan

1 Infection, coagulopathy, very short or lengthy life expectancy, distorted anatomy, patient unwillingness, medications that increase risk for bleeding (e.g., anti-angiogenesis agents such as bevacizumab), or technical expertise is not available.

Note: All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.
Discussion

NCCN Categories of Evidence and Consensus

**Category 1:** Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2A:** Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2B:** Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.

**Category 3:** Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise noted.

Overview

Pain is one of the most common symptoms associated with cancer. Pain is defined by the International Association for the Study of Pain as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in relation to such damage.\(^1\) Cancer pain or cancer-related pain distinguishes pain experienced by cancer patients from that experienced by patients without malignancies. A meta-analysis revealed that pain was reported in 59% of patients undergoing cancer treatment, in 64% of patients with advanced disease, and in 33% of patients after curative treatment.\(^2\) In addition, this is one of the symptoms patients fear most. Unrelieved pain denies patients comfort and greatly affects their activities, motivation, interactions with family and friends, and overall quality of life. There is mounting evidence in oncology that survival is linked to pain control.\(^3\)

The importance of relieving pain and the availability of effective therapies make it imperative that physicians and nurses caring for these patients be adept at the assessment and cancer pain treatment.\(^4\)-\(^6\) This requires familiarity with the pathogenesis of cancer pain, pain assessment techniques, and common barriers to the delivery of appropriate analgesia. Providers should be familiar with pertinent pharmacologic, anesthetic, neurosurgical, and behavioral interventions for treating cancer pain, as well as complimentary approaches such as physical/occupational therapy.

The most widely accepted algorithm for the treatment of cancer pain was developed by the WHO.\(^7\)-\(^8\) It suggests that patients with pain be started on acetaminophen or a nonsteroidal anti-inflammatory drug (NSAID). If this is not sufficient, the patient should be escalated to a “weak opioid,” such as codeine, and subsequently to a “strong opioid,” such as morphine. Although this algorithm has served as an excellent teaching tool, the management of cancer pain is considerably more complex than this three-tiered “cancer pain ladder” suggests.

This NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines) for Adult Cancer Pain are unique in several important ways. The NCCN Guidelines identify central principles for assessing and managing cancer pain in adults. First, they list general principles of pain management, followed by guiding principles for assessment, management/intervention, and reassessment:

**General**
- There is increasing evidence in oncology that survival is linked to symptom control and that pain management contributes to broad quality-of-life improvement. To maximize patient outcomes, pain management is an essential part of oncologic management.
- Analgesic therapy is done in conjunction with management of multiple symptoms or symptom clusters and the complex pharmacologic therapies that patients with cancer are generally prescribed.
- A multidisciplinary team may be needed.
- Psychosocial support must be available including emotional and informational support and coping skills training.
- Specific educational material must be provided to the patient and family/caregiver.
- Consider the multidimensional impact of “suffering” on patients and their families and address these concerns in a culturally respectful manner.

**Assessment**
- All patients must be screened for pain at each contact.
- Pain intensity must be quantified and quality must be characterized by the patient (whenever possible based on patient communication capacity).
Adult Cancer Pain

- Comprehensive pain assessment must be performed if new pain is present and regularly performed for persisting pain.
- Pain assessment of patient’s pain is essential with a rating scale but also includes patient reporting of qualities of the pain, breakthrough pain, treatments used and their impact on pain, patient reporting of adequate comfort, satisfaction with pain relief, provider assessment of adequacy of function, and any special issues for the patient relevant to pain treatment.

Management/Intervention
- Goals of pain management are improved comfort, function, and safety.
- Comprehensive pain management is needed, as most patients have multiple pathophysiologies and multiple symptoms.
- Prevention of expected analgesic side effects, especially constipation in the setting of opioid use, is key to effective pain treatment.
- Optimize patient and family education and physical and cognitive integrative interventions.
- For acute pain crisis, consider hospital admission to achieve patient-specific pain goals.
- Persistent cancer pain often requires treatment with regularly scheduled analgesics, and supplemental doses of analgesics are often required to manage breakthrough pain.
- For chronic pain in cancer survivors, see the NCCN Guidelines for Survivorship.

Reassessment
- Reassessment of pain intensity must be performed at specified intervals to ensure that the analgesic therapy selected is having the maximum benefit with as few adverse effects as possible.

Pathophysiologic Classification of Cancer Pain Syndromes
Different types of pain occur in cancer patients. A number of attempts have been made to classify pain according to different criteria. Pain classification includes differentiating between pain associated with tumor, pain associated with treatment, and pain unrelated to either. Acute and chronic pain should also be distinguished from each other when deciding which therapy to use. Therapeutic strategy depends on the pain pathophysiology, which is determined by patient examination and evaluation. There are two predominant mechanisms of pain pathophysiology: nociceptive and neuropathic.9,10

Nociceptive pain is the result of injury to somatic and visceral structures and the resulting activation of nociceptors. Nociceptors are present in skin, viscera, muscle, and connective tissue. Nociceptive pain can further be divided into somatic pain and visceral pain.11 Pain described as sharp, well localized, throbbing, and pressure-like is likely to be somatic nociceptive pain. It occurs often after surgical procedures or from bone metastasis. Visceral nociceptive pain is often described as more diffuse, aching, and cramping. It is secondary to compression, infiltration, or distension of abdominal or thoracic viscera.

Neuropathic pain results from injury to the peripheral or central nervous system (CNS). This type of pain might be described as burning, sharp, or shooting. Examples of neuropathic pain include pain due to spinal stenosis or diabetic neuropathy, or as an adverse effect of adjuvant analgesics. They also provide specific suggestions for titrating and rotating opioids, escalation of opioid dosage, management of opioid adverse effects, and when and how to proceed to other techniques/interventions for the management of cancer pain.
chemotherapy (eg, vincristine), radiation therapy, or following surgical injury to the nerves.

**Comprehensive Pain Assessment**

A comprehensive evaluation is essential to ensure proper pain management. Failure to adequately assess pain frequently leads to poor pain control. It is therefore important to find the cause of the pain and identify optimal therapies. This algorithm begins with the premise that all patients with cancer should be screened for pain during the initial evaluation, at regular follow-up intervals, and whenever new therapy is initiated. If pain is present on a screening evaluation, the pain intensity must be quantified by the patient (whenever possible). Since pain is inherently subjective, patients' self-reporting of pain is the current standard of care for assessment.

**Selecting Tools for Assessing Pain**

Various methods and tools exist to assess pain severity. Intensity of pain should be quantified using a numerical rating scale (ie, 0–10), visual analog scale, categorical scale, or pictorial scale (eg, The Faces Pain Rating Scale). Although pain is commonly assessed using numerical or categorical ratings, some patients may experience difficulty with these scales. The Faces Pain Rating Scale may be successful with patients who have difficulty with other scales, for example, children, the elderly, and patients with language or cultural differences or other communication barriers. If the patient is unable to verbally report pain, an alternative method to obtain pain rating and pain assessment must be utilized. In addition to pain intensity, the patient should be asked to describe the characteristics of his/her pain (ie, aching, burning).

The Brief Pain Inventory (BPI) assesses pain severity in patients with cancer in two important dimensions: intensity of pain and interference of pain with a patient’s life. Studies suggest that pain may interfere with daily functions to a different extent in patients with cancer versus those with chronic noncancer pain. As such, pain interference (ie, a measure of the impact of pain on daily functions) is of particular importance when assessing pain in patients with cancer. The BPI quantifies these measures using a 0 to 10 numerical scale. Based on these numerical ratings, cut-points have been established to categorize pain severity as mild, moderate, or severe for the purpose of treatment planning. Assessment of both pain intensity and impact of pain on daily functions should be considered when establishing patient-specific goals for comfort and function.

An additional assessment tool that has undergone psychometric evaluation is the PROMIS pain interference (PROMIS-PI) bank; early validation studies suggest the potential utility of this approach to pain assessment as an alternative to standard-of-care assessment methods based on the BPI. Additional studies are needed to assess the application of the PROMIS-PI for assessing cancer pain severity.

**Assessing Pain**

If the patient has no pain, re-screening should be performed at each subsequent visit or as requested. Identifying the presence of pain through repeated screening is essential to allow implementation of effective pain management.

If the Pain Rating Scale score is above 0, a comprehensive pain assessment is initiated. The comprehensive pain assessment should focus on the type and quality of pain; pain history (eg, onset, duration, course); pain intensity (ie, pain experienced at rest; with movement;); location; referral pattern; radiation of pain; impact of pain (ie,
interference with activities such as work, sleep, and interpersonal interactions; the associated factors that exacerbate or relieve the pain; current pain management plan; patient’s response to current therapy; prior pain therapies; breakthrough or episodic pain not controlled with existing pain regimen; important psychosocial factors (e.g., patient distress, family/caregiver and other support, psychiatric history, risk factors for undertreatment of pain); and other special issues relating to pain (e.g., meaning of pain for patient and family/caregiver; cultural beliefs toward pain, pain expression and treatment; spiritual or religious considerations and existential suffering).

Finally, the patient’s goals and expectations of pain management should be discussed, including level of comfort and function, with family/caregivers included.

In addition, a thorough physical examination and review of appropriate laboratory and imaging studies are essential for a comprehensive pain assessment. This evaluation should enable caregivers to determine if the pain is related to an underlying cause that requires specific therapy. For example, it is inappropriate to provide only opioids to a patient suffering pain from impending spinal cord compression. Without glucocorticoids and local radiation therapy, the pain is unlikely to be well-controlled, and the patient will remain at high risk for spinal cord injury.

The NCCN Panel recommends monitoring risk factors for aberrant use or diversion of pain medication, which might be identified during initial screening using tools such as SOAPP-R (Screener and Opioid Assessment for Patients with Pain-Revised) or ORT (Opioid Risk Tool). The SOAPP was developed to predict which patients, being considered for long-term opioid therapy, may exhibit aberrant medications behaviors in the future. SOAPP-R is a revised version of the SOAPP. Similar to the SOAPP-R, the ORT assesses the risk of aberrant behaviors when patients are prescribed opioid medication for chronic pain with a high degree of sensitivity and specificity for determining which individuals are at risk for opioid abuse. SOAPP-R and ORT discriminate between high-risk and low-risk patients. High-risk score on the SOAPP-R or ORT correlate with an increased likelihood of drug abuse. Randomly administered urine drug screens and prescription monitoring programs can also be used to monitor for aberrant use or diversion of pain medications.

The endpoint of comprehensive pain assessment is to diagnose the etiology and pathophysiology (somatic, visceral, or neuropathic) of the pain. Treatment must be individualized based on clinical circumstances and patient wishes, with the goal of maximizing function and quality of life.

**Management of Adult Cancer Pain**

For management of cancer-related pain in adults, the algorithm distinguishes three levels of pain intensity based on a 0 to 10 numerical value obtained using a numerical or pictorial rating scale (with 0 being no pain to 10 being the worst pain). The three levels of pain intensity referred to in the algorithm are mild pain (1–3); moderate pain (4–6); and severe pain (7–10).

The NCCN Panel recommends that providers consider all pain management interventions in the context of patient-specific goals for comfort and function, as well as safety. Patients presenting with an acute pain crisis may be candidates for hospital admission to achieve patient-specific goals for comfort and function. It is important to separate pain related to an oncologic emergency from pain not related to an oncologic emergency.

In addition, the algorithm distinguishes pain not related to oncologic emergencies in patients not chronically taking opioids (opioid naïve)
from patients who have previously or are chronically taking opioids for cancer pain (opioid tolerant). It also distinguishes anticipated procedure-related pain and anxiety.

According to the U.S. Food and Drug Administration (FDA), “patients considered opioid tolerant are those who are taking at least: 60 mg oral morphine/day, 25 mcg transdermal fentanyl/hour, 30 mg oral oxycodone/day, 8 mg oral hydromorphone/day, 25 mg oral oxymorphone/day, or an equianalgesic dose of another opioid for one week or longer.” Therefore, patients who do not meet the above definition of opioid tolerant, and who have not had opioid doses at least as much as those listed above for a week or more, are considered to be opioid naïve.

Management of Pain Related to Oncologic Emergency

An oncologic emergency is defined as a life-threatening event directly or indirectly related to a patient's cancer or its treatment. Pain related to an oncologic emergency includes pain due to bone fracture or impending fracture of weight-bearing bone; epidural or leptomeningeal metastases seen in patients with advanced cancers; pain related to infection; or obstructed or perforated viscus. Pain associated with oncologic emergency should be treated directly while proceeding with the treatment of the underlying condition.

Management of Pain Not Related to Oncologic Emergency in Opioid-Naïve Patients

For all patients experiencing pain, care providers should provide psychosocial support and begin educational activities. Psychosocial support is needed to ensure that patients encountering common barriers to appropriate pain control (eg, fear of addiction or side effects, inability to obtain opioids) or needing assistance in managing additional problems (eg, depression, rapidly declining functional status) receive appropriate aid. The patient and the family/caregiver must be educated regarding pain management and related issues. Patients should be reevaluated at each contact and as needed to meet their goals for comfort and function.

Although pharmacologic analgesics, including non-opioids (such as NSAIDS or acetaminophen), opioids, and adjuvant analgesics (such as antidepressants, anticonvulsants, topical agents, and corticosteroids) are the cornerstone of cancer pain management, they are not always adequate and are associated with many adverse effects. Thus, they often are necessitating the implementation of additional therapies or treatments. Optimal use of nonpharmacologic integrative interventions (physical, cognitive modalities, and spiritual) may serve as valuable additions to pharmacologic interventions.

Opioid-naïve patients (those who are not chronically receiving opioids on a daily basis) experiencing severe pain (ie, pain intensity rating 7–10) should receive rapid titration of short-acting opioids (see section below on Opioid Prescription, Titration, and Maintenance). Short-acting formulations have the advantage of rapid onset of analgesic effect. The route of administration of opioid is decided (oral vs. intravenous) based on what is best suited to the patient’s ongoing analgesic needs.

A number of adverse effects are potentially associated with the use of opioid analgesics. The management of these common opioid-induced adverse effects should be started simultaneously with initiation of opioid therapy. Opioid-induced bowel dysfunction should be anticipated and treated prophylactically with a stimulating laxative to increase bowel motility, with or without stool softeners as indicated. Addition of adjuvant analgesic for specific pain syndromes should be considered for all groups of patients. Adjuvant analgesics are drugs used to enhance the effects of opioids or NSAIDs.
For opioid-naïve patients, whose pain intensity is moderate with a rating between 4 and 6 at presentation, the pathways are quite similar to those for pain intensity of 7 to 10 (above). The main differences include treatment beginning with slower titration of short-acting opioids.

Opioid-naïve patients experiencing mild pain intensity (rating between 1–3) should receive treatment with nonopioid analgesics such as NSAIDs or acetaminophen or treatment with consideration of slower titration of short-acting opioids.

Patients with chronic persistent pain controlled by stable doses of short-acting opioids should be provided with round-the-clock extended release or long-acting formulation opioids with provision of a "rescue dose" to manage break-through or transient exacerbations of pain. The rescue dose is usually equivalent to 10% to 20% of the total daily dose given every hour as needed. Opioids with a rapid onset and short duration are preferred as rescue doses. The repeated need for rescue doses per day may indicate the necessity to adjust the baseline treatment.

Management of Pain Not Related to Oncologic Emergency in Opioid-Tolerant Patients

Opioid-tolerant patients are those chronically taking opioids for pain relief. According to the FDA, opioid-tolerant patients “are those who are taking at least: 60 mg oral morphine/day, 25 mcg transdermal fentanyl/hour, 30 mg oral oxycodone/day, 8 mg oral hydromorphone/day, 25 mg oral oxymorphone/day, or an equianalgesic dose of another opioid for one week or longer.”

In opioid-tolerant patients who are experiencing breakthrough pain of intensity greater than or equal to 4, a pain intensity less than 4 but whose goals of pain control and function are not met, in order to achieve adequate analgesia, the previous 24-hour total oral or IV opioid requirement must be calculated and the new rescue dose must be increased by an opioid dose equivalent to 10% to 20% of total opioid taken in the previous 24 hours.

Efficacy and adverse effects should be assessed every 60 minutes for orally administered opioids and every 15 minutes for intravenous opioids to determine a subsequent dose. Upon assessment, if the pain score remains unchanged or is increased, administration of 50% to 100% of the previous rescue dose of opioid is recommended. If the pain score decreases to 4 to 6, the same dose of opioid is repeated and reassessment is performed at 60 minutes for orally administered opioids and every 15 minutes for intravenously administered opioids. If pain score remains unchanged upon reassessment after 2 to 3 cycles of the opioid, in patients with moderate to severe pain, changing the route of administration from oral to intravenous or alternate management strategies can be considered. If the pain score decreases to 0 to 3, the current effective dose of either oral or intravenous opioid is administered “as needed” over an initial 24 hours before proceeding to subsequent management strategies.

Management of Procedure-Related Pain and Anxiety

Procedure-related pain represents an acute short-lived experience that may be accompanied by a great deal of anxiety. Procedures reported as painful include bone marrow aspirations; wound care; lumbar puncture; skin and bone marrow biopsies; and intravenous line, arterial line, and central line injections and manipulations. Much of the data available on procedure-related pain come from studies on pediatric patients with cancer, which are then extrapolated to adults.

Interventions to manage procedure-related pain should take into account the type of procedure, the anticipated level of pain, and other factors.
individually characteristics of the patient, such as age and physical condition. The interventions may be multimodal and may include pharmacologic and/or nonpharmacologic approaches. Supplemental doses of analgesics should be given in anticipation of procedure-related pain. Anxiolytics are drugs used for the treatment of anxiety and its related psychological and physical symptoms. Anxiolytics should be given preemptively for control of procedure-related anxiety when feasible.

Local anesthetics can be used to manage procedure-related pain with sufficient time for effectiveness as per package inserts. Examples of local anesthetics include lidocaine, prilocaine, and tetracaine. Physical approaches such as cutaneous warming, laser or jet injection, and ultrasound (US) may accelerate the onset of cutaneous anesthesia. Sedatives may also be used. However, deep sedation and general anesthesia must be carried out only by trained professionals. In addition, use of nonpharmacologic interventions may be valuable in managing procedure-related pain and anxiety. The major goal of nonpharmacologic interventions that include physical and cognitive modalities is to promote a sense of control increasing hope and reducing helplessness that many patients with pain from cancer experience.

Patients usually tolerate procedures better when they know what to expect. Therefore, patients and family members/caregivers should receive written instructions for managing pain. Pre-procedure patient education that includes procedure details and pain management strategies is essential. Patients and family members/caregivers should receive written information regarding pain management options.

Subsequent Management of Cancer Pain

The subsequent treatment is based upon the patient’s continued pain rating score. All approaches for all pain intensity levels must include administration of regular doses of opioids with rescue doses as needed and management of constipation, coupled with psychosocial support and education for patients and their families.

If the pain at this time is severe, unchanged, or increased, the working diagnosis must be re-evaluated and comprehensive pain assessment must be carried out. For patients unable to tolerate dose escalation of their current opioid due to adverse effects, an alternate opioid must be considered. Addition of adjuvant analgesics should be re-evaluated to either enhance the analgesic effect of the opioids or in some cases to counter the adverse effects associated with the opioids. Optimal use of nonpharmacologic integrative interventions (physical, cognitive modalities, and spiritual) may serve as valuable additions to pharmacologic interventions. Given the multifaceted nature of cancer pain, additional interventions for specific cancer pain syndromes and specialty consultation must be considered to provide adequate analgesia. If the patient is experiencing moderate pain of intensity of 4 to 6 and if he or she has adequate analgesic relief on his or her current opioid, the current titration of the opioid may be continued or increased. In addition, as with patients experiencing severe pain, addition of adjuvant analgesics; additional interventions for specific cancer pain syndromes; and specialty consultation must be considered.

For patients experiencing mild pain, if they have adequate analgesia but intolerable or unmanageable adverse effects, the analgesic dose may be reduced by 10% to 25% of the current opioid dose. Addition of adjuvant analgesics may be considered.
Ongoing Care

Although pain intensity ratings will be obtained frequently to evaluate opioid dose increases, a formal re-evaluation to assess patient goals of comfort and function is mandated at each contact.

If an acceptable level of comfort and function has been achieved for the patient, and 24-hour opioid requirement is stable, the NCCN Panel recommends converting to an extended-release oral medication (if feasible) or other extended-release formulation (i.e., transdermal fentanyl). The subsequent treatment is based upon the patient’s continued pain rating score. Rescue doses of the short-acting formulation of the same long-acting drug may be provided during maintenance therapy for the management of pain in cancer patients not relieved by extended-release opioids.

Routine follow-up should be done during each outpatient contact or at least each day for inpatients depending on patient conditions and institutional standards.

System-related barriers exist that include cost of analgesics and a lack of access to/availability of analgesics, particularly in minority neighborhoods or for those who are economically disadvantaged. Studies have documented the inequalities that persist since those with financial burdens or minorities have less access to pain treatment. The NCCN Panel recommends addressing such system barriers.

The patients must be provided with a written follow-up pain plan, including prescribed medications. It is important to ensure that the patient has adequate access to prescribed medications and maintains communication and coordination of care with a pain specialist and relevant providers, especially during transitions between sites of care. It should be clarified with the patient regarding which clinician will be prescribing his/her ongoing care. Equally important is monitoring for the use of analgesics as prescribed, especially in patients with risk factors for or history of abuse.

If an acceptable level of comfort and function has not been achieved for the patients, universal screening and assessment must be carried out and additional strategies for pain relief must be considered.

Pain in Cancer Survivors

Chronic pain in cancer survivors may have a unique etiology and symptomatology compared with pain experienced by patients with cancer. Up to a third of post-treatment cancer survivors experience chronic pain, which can cause psychological distress and impact quality of life. For more information on pain in cancer survivors as well as other survivor-related issues, please see the NCCN Guidelines for Survivorship.

Pharmacologic Interventions

Opioids and Miscellaneous Analgesics

Selecting an Appropriate Opioid

While starting therapy, attempts should be made to determine the underlying pain mechanism and diagnose the pain syndrome. Optimal analgesic selection will depend on the patient’s pain intensity, any current analgesic therapy, and concomitant medical illness(es). An individual approach should be used to determine opioid starting dose, frequency, and titration in order to achieve a balance between pain relief and medication adverse effects.

Pure agonists (such as morphine, oxycodone, oxymorphone, and fentanyl) are the most commonly used medications in the management of cancer pain. The short half-life opioid agonists (morphine, hydromorphone, fentanyl, and oxycodone) are preferred, because they...
can be more easily titrated than the long half-life analgesics (methadone and levorphanol).\textsuperscript{42}

Morphine is a mu-opioid receptor agonist and weak kappa receptor agonist. Morphine is available in a wide range of formulations and routes, including oral, parenteral, and rectal delivery.\textsuperscript{43} In a patient who has not been exposed to opioids in the past, morphine is generally considered the standard starting drug of choice.\textsuperscript{44,45} Oral administration is the preferred route. An initial oral dose of 5 to 15 mg of oral short-acting morphine sulfate or equivalent is recommended for opioid-naïve patients. Patients presenting with severe pain needing urgent relief should be treated with parenteral opioids, usually administered by the intravenous (IV) route or the subcutaneous (SC) route. If given parenterally, the equivalent dose is one-third of the oral dose.\textsuperscript{46} An initial dose of 2 to 5 mg of IV morphine sulfate or equivalent is recommended for opioid-naïve patients. Morphine-6-glucuronide, an active metabolite of morphine, contributes to analgesia and may worsen adverse effects as it accumulates in patients with renal insufficiency.\textsuperscript{47,48}

Fentanyl is a highly lipid-soluble mu-opioid receptor agonist that can be administered by the parenteral, spinal, transdermal, transmucosal, buccal, and intranasal routes.\textsuperscript{49} Transdermal fentanyl is not indicated for rapid opioid titration and only should be recommended after pain is controlled by other opioids in opioid-tolerant patients.\textsuperscript{50} It is usually the treatment of choice for patients who are unable to swallow, patients with poor tolerance to morphine, and patients with poor compliance. Conversion from intravenous fentanyl to transdermal fentanyl can be accomplished effectively using a 1:1 conversion ratio.\textsuperscript{51} Transmucosal fentanyl may be considered in opioid-tolerant patients for brief episodes of incident pain not attributed to inadequate dosing of around-the-clock opioid. Data do not support a specific transmucosal fentanyl dose equianalgesic to other opioids or between different transmucosal formulations. There are increasing data showing that buccal fentanyl is effective in treatment of breakthrough pain in patients with cancer.\textsuperscript{52-54}

Hydrocodone is a mu- and delta-opioid receptor agonist that may be approximately equipotent with oral morphine; however, its equivalence data are not substantiated.\textsuperscript{59} Clinical experience suggests use as a mild, initial use opioid, but effective dose may vary. It is available only in combination with oral agents such as acetaminophen or ibuprofen.

Codeine is a weak mu- and delta-opioid receptor agonist with little direct analgesic effect; it is a prodrug that is metabolized to codeine-6-glucuronide, norcodeine, morphine, morphine-3-glucuronide, morphine-6-glucuronide, and normorphine.\textsuperscript{49,55} This process is largely through the action of the cytochrome P450 enzyme, CYP2D6. It is important to note that CYP2D6 exhibits polymorphism between various ethnic groups and between individuals. A significant portion of individuals who are poor metabolizers would obtain reduced or no analgesic effects from codeine administration.\textsuperscript{56} Conversely, rapid metabolizers may experience toxicity after codeine administration from more rapid morphine production.\textsuperscript{56}

Hydromorphone is primarily a mu-opioid receptor agonist and weak delta-opioid receptor agonist that has properties similar to morphine and is available in oral tablets, liquids, suppositories, and parenteral formulations.\textsuperscript{49,57} There is some evidence suggesting that the metabolite of hydromorphone may lead to opioid neurotoxicity, including myoclonus, hyperalgesia, and seizures.\textsuperscript{58} This metabolite may be more neurotoxic than the morphine metabolite.\textsuperscript{59}
Morphine, hydromorphone, or codeine should be used with caution in patients with fluctuating renal function due to potential accumulation of renally cleared metabolites that may cause neurologic toxicity.\(^{60,61}\)

Oxycodone is an opioid with agonist activity at the mu-, delta-, and kappa-opioid receptors and is available in immediate- and extended-release formulations.\(^{62-64}\) Oxycodone is also available in combination with acetaminophen; therefore, the dosage must be monitored for safe limits to avoid potential hepatic toxicity.

Oxymorphone is an opioid agonist that acts primarily at the mu-opioid receptor. It is available in immediate- and extended-release formulations.\(^{49,64,65}\)

Methadone is a mu-opioid receptor agonist that also acts as an antagonist at NMDA receptors; it is commercially available in multiple strength oral tablets or oral solution.\(^{49}\) Individual variations in methadone pharmacokinetics (long half-life ranging from 8 to more than 120 hours) make its usage very difficult in cancer patients.\(^{64}\) Due to its long half-life, high potency, and inter-individual variations in pharmacokinetics, methadone should be started at doses lower than calculated and slowly titrated upwards with provision of adequate, short-acting, breakthrough pain medications during the titration period. The NCCN Guidelines recommend monitoring for drug accumulation and adverse effects, particularly over the first 4 to 5 days, and caution that steady state may not be reached for several days to 2 weeks. The dosing ratio between methadone and morphine or other opioids, as well as conversion from another opioid to methadone, is not simple.\(^{67,68}\)

Generally, randomized controlled trial (RCT) data has demonstrated that methadone has similar analgesic efficacy and tolerability to morphine for treating cancer pain.\(^{69}\) Studies show that outpatient initiation and rotation to methadone can be successfully done in cancer patients without serious adverse effects.\(^{70}\) A recent retrospective, observational study suggested that very-low-dose methadone (ie, ≤15 mg/d), in conjunction with adjuvant haloperidol, provided pain control without opioid-induced hyperalgesia or required opioid dose escalation.\(^{71}\) Currently, no prospective, randomized trials have investigated this approach.

The NCCN Panel cautions and advises practitioners to consult a pain management specialist if they are unfamiliar with methadone prescribing or if individual patient considerations necessitate very rapid switching to or from methadone.

There is evidence suggesting that high doses of methadone (120 mg and above) may lead to QTc prolongation and torsades de pointes, which if uncorrected may lead to sudden cardiac death.\(^{72-74}\) Oral methadone is commonly used for the treatment of cancer pain, and the average dosing appears to be much lower than is used to treat opioid dependency and chronic nonmalignant pain. A recent study conducted in cancer patients suggests that QT interval changes exist commonly at baseline and are not changed with the addition of methadone.\(^{75}\) However, physicians initiating methadone should be aware of the drug interactions. The NCCN Panel recommends a baseline and follow-up echocardiogram for patients treated with methadone doses >100 mg/day and for patients with cardiac disease, or when methadone is used in patients taking other medications also known to prolong QTc (including tricyclic anti-depressants). QTc greater than or equal to 450 may indicate the need to reduce or discontinue the methadone dose.

Methadone use should be initiated by physicians with experience and expertise in its use. Patients and their families may need to be educated about analgesic utility of methadone. Some may only be
familiar with methadone use for maintenance of addiction and be unaware of its utility as a potent opioid analgesic.

Levorphanol is a mu-, delta-, and kappa-opioid receptor agonist. Like methadone, levorphanol also acts as an antagonist at NMDA receptors, but it has a shorter half-life and more predictable metabolism.\(^7\) Similar to methadone, levorphanol varies in its dosing equivalence with morphine; in a case series of 20 patients receiving palliative or hospice care, the morphine to levorphanol conversion factors were listed as 12:1 for morphine doses of less than 100 mg, 15:1 for morphine doses between 100 mg and 299 mg, 20:1 for morphine doses between 300 mg and 599 mg, and 25:1 for morphine doses over 600 mg.\(^7\) For certain populations (eg, the elderly), levorphanol may offer similar benefits to methadone but with lessened prescribing complexities and adverse effects.\(^7\) One study also demonstrated potential efficacy of levorphanol for treating neuropathic pain.\(^7\)

**Selecting Miscellaneous Analgesics**

Tramadol and tapentadol are atypical opioids with a dual mechanism of action on opioid receptors and neurotransmitter reuptake (eg, norepinephrine, serotonin).

Tramadol is a weak mu-opioid receptor agonist with some norepinephrine and serotonin reuptake inhibition that is indicated for treating moderate to moderately severe pain.\(^7\) Tramadol is available as immediate-release and extended-release formulations. Tramadol should be avoided in patients receiving selective serotonin reuptake inhibitors (SSRIs) or tricyclic antidepressants. The NCCN Panel recommends a maximum daily dose of 400 mg (100 mg four times a day) for adults with normal hepatic and renal function. Lower doses are recommended for older adults (75 years and older) and those with hepatic and/or renal dysfunction, to reduce the risk of seizures.

Tramadol is less potent than other opioids and is considered to be approximately 1/10th as potent as morphine.\(^7\) One nonrandomized, observational study in patients with cancer found comparable analgesic efficacy of high-dose tramadol (ie, ≥300 mg/d) and low-dose morphine (ie, ≤60 mg/d), but observed higher rates of constipation, neuropsychological symptoms, and pruritus in patients receiving low-dose morphine.\(^8\) However, in a double-blind study of cancer patients, tramadol produced more adverse effects, including vomiting, dizziness, and weakness, than hydrocodone and codeine.\(^8\)

Tapentadol is an opioid that binds to the µ opioid receptor and inhibits norepinephrine reuptake.\(^8\) It is available as extended-release and immediate-release formulations and is used for treatment of moderate to severe pain. Typical doses would start at 50 to 100 mg orally (PO) every 4 hours as needed, with a maximal daily dose of 500 mg per day (if using the extended release) or 600 mg per day (if using the immediate release only) due to lack of published data regarding higher doses. In comparative phase II-III studies the efficacy and safety of tapentadol has been demonstrated compared with placebo and oxycodone for non-cancer pain.\(^8\) There are some data suggesting that tapentadol may have a lower incidence of gastrointestinal adverse effects than oxycodone.\(^8\) To date, no randomized trial evaluating the efficacy of tapentadol is available in cancer patients. The first study reporting data from cancer pain patients was a small, prospective, open-label study with 50 opioid-naïve cancer pain patients, 39 of whom completed the entire study.\(^8\) Results of the study showed that compared with the placebo, tapentadol at 100 mg daily dose is well tolerated and was effective in decreasing pain intensity from baseline and improving quality of life.\(^8\)

Transdermal buprenorphine, a partial µ-agonist, has been approved for chronic pain. Although RCT data on buprenorphine for treating cancer
pain is somewhat limited, several case series, prospective uncontrolled studies, and a few randomized trials support its use in cancer-related pain. Studies of buprenorphine suggest that it exhibits a ceiling to analgesic efficacy thereby limiting its use in palliative care. It may precipitate withdrawal symptoms if administered to individuals currently taking a high-dose opioid. FDA guidelines recommend limiting dose to a maximum of 20 µg per hour due to concern for QT prolongation. Because the dose conversion from other opioids to buprenorphine can be complex, the NCCN Panel suggests that providers consider a pain specialty consultation for complex cases.

Ketamine is a non-competitive N-methyl D-aspartate receptor antagonist that blocks glutamate. Low (sub-anesthetic) doses produce analgesia and modulate central sensitization, hyperalgesia, and opioid tolerance. There are only limited data regarding the use of ketamine as an adjuvant to opioids for management of cancer pain. A double-blind, randomized, placebo-controlled trial found no significant difference between the outcomes of patients treated for cancer pain with ketamine versus placebo.

The following agents are not recommended for cancer patients: 1) mixed agonist-antagonists (eg, butorphanol, pentazocine); 2) meperidine; and 3) placebos. Mixed agonist-antagonist should not be used in combination with opioid agonist drugs for cancer pain management. Converting from an agonist to an agonist-antagonist could precipitate the abstinence syndrome (a withdrawal crisis) if given to a patient who is physically dependent on a pure opioid agonist. Meperidine is contraindicated for chronic pain, especially in patients with impaired renal function or dehydration, because accumulation of metabolites that are cleared renally may result in neurotoxicity (seizures) or cardiac arrhythmias. Use of placebo in the treatment of pain is unethical.

Selecting a Route of Administration
The least invasive, easiest, and safest route of opioid administration should be provided to ensure adequate analgesia. Oral is the preferred route of administration for chronic opioid therapy. The oral route should be considered first in patients who can take oral medications unless a rapid onset of analgesia is required or the patient experiences adverse effects associated with the oral administration. Continuous parenteral infusion, IV or SC, is recommended for patients who cannot swallow or absorb opioids enterally. Opioids, given parenterally, may produce fast and effective plasma concentrations in comparison with oral or transdermal opioids. Intravenous route is considered for faster analgesia because of the short lag-time between injection and effect (peak 15 minutes) in comparison with oral dosing (peak 60 minutes). The SC route has a slower onset and lower peak (30 minutes) effect when compared with IV route.

Opioid Prescription, Titration, and Maintenance
The appropriate dose of opioid is based on the patient’s pain intensity and his/her goals without causing undesirable and unmanageable adverse drug effects.

The physicians should be aware of potential drug-drug and drug-disease interactions while determining the treatment plan. For a summary of common drug-drug interactions between chemotherapeutics, analgesics, and other commonly prescribed medications, see Table 1. The patient’s goals and quality of life should also be considered when modifying the treatment plan.

The following methods of ongoing analgesic administration are widely used in clinical practice: “around the clock,” “as needed,” and
“patient-controlled analgesia.” For most patients, dosing should be used for continuous pain relief. Additional doses of opioid may be required for pain not relieved by a regular schedule of long-acting (eg, extended release) opioid.

The NCCN Panel recommends considering opioid rotation if pain is inadequately controlled or persistent adverse effects from current therapy occur. Other indications for switching to a different opioid include out-of-pocket costs and limitations based upon insurance formularies.

For patients who have intermittent pain with pain-free intervals, immediate-release opioids can be administered on an “as needed” basis with the exception of methadone due to its long duration of effect. The “as needed” method is also used when rapid dose titration is required. The patient-controlled analgesia technique allows a patient to control a device that delivers a bolus of analgesic “on demand” (according to, and limited by, parameters set by a physician).

Breakthrough pain is defined as pain that fails to be controlled or “breaks through” a regimen of regularly scheduled opioid and may be further categorized as: incident pain that is associated with specific activities or events, potentially managed with “rescue doses” of short-acting opioid given in anticipation of those events; end-of-dose failure pain that recurs toward the end of dosing interval for regularly scheduled opioid, potentially managed by increasing the dose or frequency of regularly scheduled opioid; and uncontrolled, persistent pain that is routinely uncontrolled by existing regularly scheduled opioid, potentially managed by adjusting dose of regularly scheduled opioid. Although the literature on useful therapies for breakthrough cancer pain is relatively small, multiple RCTs suggest that buccal, sublingual, or oral/nasal transmucosal formulations of fentanyl are effective options for managing episodic breakthrough pain (reviewed in 97,98).

The NCCN Panel also recommends monitoring for aberrant medication drug-related behaviors over the course of treatment using tools such as COMM (Current Opioid Misuse Measure). The COMM tool helps clinicians identify whether a patient, currently on long-term opioid therapy, is exhibiting aberrant behaviors associated with misuse of opioid medications.99 It examines concurrent misuse; in contrast, SOAPP-R or ORT is helpful in predicting which patients being considered for long-term opioid therapy may exhibit aberrant medications behaviors in the future.

**Initiating Short-Acting Opioids in Opioid-Naïve Patients**

The route of administration of opioid (oral or intravenous) must be selected based on the patient’s needs. The NCCN Guidelines for Adult Cancer Pain management provide guidance for initiating short-acting opioids in opioid-naïve and opioid-tolerant patients.

For opioid-naïve patients, experiencing pain intensity of greater than or equal to 4 or a pain intensity less than 4 but whose goals of pain control and function are not met, an initial dose of 5 to 15 mg of oral morphine sulfate or 2 to 5 mg of intravenous morphine sulfate or equivalent is recommended. Assessment of efficacy and adverse effects should be performed every 60 minutes for orally administered opioids and every 15 minutes for intravenously administered opioids to determine a subsequent dose. Upon assessment, if the pain score remains unchanged or is increased, to achieve adequate analgesia, it is recommended that the dose be increased by 50% to 100% of the previous opioid dose. If the pain score decreases to 4 to 6, the same opioid dose is repeated and reassessment is performed at 60 minutes for orally administered opioids and every 15 minutes for intravenously administered opioids.
Adult Cancer Pain

inadequate response is seen in patients with moderate to severe pain, upon reassessment after 2 to 3 cycles of the opioid, changing the route of administration from oral to intravenous or subsequent management strategies can be considered. If the pain score decreases to 0 to 3, the current effective dose of opioid is administered “as needed” over an initial 24 hours before proceeding to subsequent management strategies.

Opioid Adverse Effects
A number of adverse effects are associated with the use of opioid analgesics. Constipation, nausea and vomiting, pruritus, delirium, respiratory depression, motor and cognitive impairment, and sedation are fairly common, especially when multiple agents are used.\textsuperscript{100-105} Each adverse effect requires a careful assessment and treatment strategy. Management of opioid-induced adverse effects is integral to opioid pain management.\textsuperscript{100,106-114}

Constipation can almost always be anticipated with opioid treatment and patients do not develop tolerance to constipation; therefore, administration of prophylactic bowel regimen is recommended. However, there is not much evidence on which to base the selection of the most appropriate prophylactic bowel regimen. There is one study showing that addition of a stool softener, such as docusate to the laxative, sennosides, was less effective than administering laxative, sennosides alone.\textsuperscript{115} Therefore for prophylaxis, the NCCN Adult Cancer Pain Guidelines Panel Members recommend a stimulant laxative with or without a stool softener or a capful of polyethylene glycol (PEG) with 8 oz of water two times daily along with maintaining adequate fluid intake. While maintaining adequate dietary fiber intake is recommended, supplemental medicinal fiber, such as psyllium, is ineffective and unlikely to reduce opioid-induced constipation.

Once constipation develops, the cause and severity of constipation must be assessed to rule out obstruction. Stool softeners or laxatives may be titrated as needed with the goal of achieving one non-forced bowel movement every 1 to 2 days. Adjuvant analgesics may be considered to allow reduction of the opioid dose.

If constipation persists, the cause and severity of constipation must be assessed again to rule out bowel obstruction or impaction. Adding stimulant laxatives, such as magnesium-based products, bisacodyl (available in tablets or suppositories), or osmotic laxatives (such as sorbitol, lactulose, and PEG) may be helpful. Opioid rotation to fentanyl or methadone may be considered. Prokinetic agents such as metoclopramide enhance gastric antral contractility and may be useful in managing persistent constipation. However, chronic use of metoclopramide may be limited due to concern for neurologic complications, including tardive dyskinesia. Enema with fleet, saline, or tap water may be helpful as it dilates the bowel, stimulates peristalsis, and lubricates the stool to encourage a bowel movement. When response to laxative therapy has not been sufficient in patients with advanced illness, methylnaltrexone, an opioid antagonist that works on receptors in the gastrointestinal system and is given subcutaneously, can be used as a rescue when constipation is clearly related to opioid therapy.\textsuperscript{116-120} Neuraxial analgesics, neuroablative techniques, or other interventions to decrease pain and/or reduce systemic opioid dose may also be considered to reduce the adverse effects.

For patients with a prior history of opioid-induced nausea, prophylactic treatment with antiemetic agents is highly recommended. If nausea develops, other causes of nausea (eg, constipation, CNS pathology, chemotherapy, radiation therapy, hypercalcemia) must be assessed. Effective agents that may be considered include benzodiazepines such as prochlorperazine or thiethylperazine or dopamine receptor
antagonists such as metoclopramide or haloperidol. If nausea persists despite an as-needed regimen, administer antiemetics around the clock for 1 week, and then change dosing as needed. When managing opioid-induced persistent nausea, instead of replacing one antiemetic with another, adding therapies that target different mechanisms of action, resulting in a synergistic effect may be helpful. Adding serotonin receptor antagonists such as granisetron or ondansetron may be helpful. Corticosteroids can also be quite beneficial for reducing opioid-induced nausea and vomiting, and in particular have been found to be effective in combination with metoclopramide and ondansetron. If nausea persists for longer than a week, the cause of nausea needs to be reassessed and opioid rotation must be considered.

Pruritus or itchiness is a particularly common and distressing complaint. Pruritus occurs in 10% to 50% of patients receiving opioids. Even in the presence of attentive skin care, opioids can produce recalcitrant pruritus. If pruritus develops, other causes of pruritus such as use of any other medication must first be assessed. Pruritus is more likely to occur early in the course of treatment. Antihistamines such as diphenhydramine or promethazine may be beneficial. If pruritus persists, consider changing to another opioid if symptomatic management has failed. Opioid antagonists have also proven useful in the management of patients whose pruritus is not relieved by antihistamines. Mixed agonist/antagonists (eg, nalbuphine) can be used to treat opioid-induced pruritus. The µ-receptor antagonists (eg, naloxone) are also used to reverse the effects of opioid-induced adverse effects, and careful dose titration can produce relief without reversing analgesic efficacy.

Sedation may hinder the achievement of dose titration of opioids to levels that provide adequate analgesia. If opioid-induced sedation develops and persists for over a week, it may be managed by administration of psychostimulants such as methylphenidate, dextroamphetamine, or modafinil or by adding caffeine. When using CNS stimulants for sedation, the dosing should be limited to morning and early afternoon to avoid insomnia at night.

Delirium is a pathophysiologic condition characterized by altered consciousness and inattention, cognitive dysfunction, and disturbed psychomotor behavior. Delirium may be treated with various interventions, for example adding a neuroleptic drug such as haloperidol, olanzapine, or risperidone or switching to another opioid. Studies have shown that stable doses of opioids (>2 weeks) are not likely to interfere with psychomotor and cognitive function, but these functions should be monitored during analgesic administration and titration.

Respiratory depression is another adverse effect that is feared both by physicians and patients. The physicians should be aware that patients with limited cardiopulmonary reserve are more susceptible and hypercarbia occurs before hypoxia. Naloxone remains a useful antidote for the reversal of opioid-induced respiratory and CNS depression, but should be administered cautiously so as not to precipitate acute opioid withdrawal syndrome in the opioid-tolerant patient.

The details of prophylactic regimens and other measures to prevent opioid-induced adverse effects are provided in the algorithms on the page titled Management of Opioid Adverse Effects.

**Opioid Rotation**

No single opioid is optimal for all patients. If opioid adverse effects are significant, an improved balance between analgesia and adverse effects might be achieved by changing to an equivalent dose of an
alternative opioid. This approach is known as opioid rotation. It is important to consider relative effectiveness when switching between oral and parenteral routes to avoid subsequent overdosing or under-dosing. Equianalgesic dose ratios, opioid titration and maintenance, and clinical examples of converting from one opioid to another are listed in the algorithms on the page titled Opioid Principles, Prescribing, Titration, and Maintenance.

Opioids and Risk Evaluation and Mitigation Strategy
While opioids are the principle analgesics for management of moderate to severe pain, they pose risks to patients and society. The abuse of opioids is also an increasing concern. In the United States, poisoning is now the leading cause of death from injuries and 89% of poisonings are related to drugs. According to the Centers for Disease Control and Prevention (CDC), 75% (16,651 of 22,134) of all pharmaceutical-related overdose deaths occurring in 2010 involved opioid analgesics. While it is important to ensure that opioids continue to be prescribed for patients for whom they are appropriate, it is also essential to ensure that these drugs are prescribed carefully. To reduce addiction, misuse, abuse, overdose, and death the FDA is establishing Risk Evaluation and Mitigation Strategy (REMS) programs for select opioid products. The principal recommendations of opioid REMS programs are educating the provider, patient, and family/caregiver.

The highlights of provider responsibilities included in the REMS are:
- Establishing patient-specific goals of opioid analgesic therapy and regularly evaluating therapeutic opioid response to guide further therapy.
- Evaluating each patient for risk factors associated with opioid misuse or abuse.
- Educating each patient on safe use, storage, and disposal of opioid.
- Routinely monitoring patients for opioid misuse or abuse.

The REMS programs are currently in place for all transmucosal fentanyl, extended-release (ER) or long-acting (LA) opioid analgesics, sublingual buprenorphine, and tapentadol. The FDA has approved shared system REMS for all transmucosal immediate-release fentanyl (TIRF) products and for all ER and LA opioid analgesics. The TIRF REMS was originally approved in December 2011 and was most recently updated in November 2013. The ER and LA Opioid Analgesics REMS was originally approved in July 2012 and was most recently updated in April 2013. The REMS for fentanyl products require a patient-prescriber agreement that requires patient education, and the ER and LA Opioid Analgesics REMS includes a patient counseling document. The complete list of currently approved REMS is available on the FDA website.

It is expected that drug manufacturers of all extended-release and long-acting opioids will meet the REMS requirement by providing educational grants for accredited entities to providing continuing education programs to prescribers. All prescribers are encouraged to discuss the risks and benefits of these products with their patients. A patient counseling document approved with the REMS will be made available by the manufacturers to assist the prescribers in having these discussions.

Additional Pharmacologic Therapies for Cancer Pain Syndromes
Opioids alone may not provide the optimal therapy, but when used in conjunction with nonopioid analgesics (such as an NSAID) or adjuvant analgesics (antidepressants, anticonvulsants, topical agents, and corticosteroids) along with psychologic and physical approaches, they can help to improve patient outcomes.
Adjuvant Analgesics for Neuropathic Pain

The term adjuvant refers to medications that are coadministered to manage an adverse effect of an opioid or to adjuvant analgesics that are added to enhance analgesia. These drugs can be helpful for patients whose pain is only partially responsive to opioids.

Clinically, adjuvant analgesics consist of a diverse range of drug classes, including anticonvulsants (e.g., gabapentin, pregabalin), antidepressants (e.g., SSRIs, serotonin-norepinephrine reuptake inhibitors, tricyclic antidepressants), corticosteroids, and local anesthetics/topical agents (e.g., topical lidocaine patch).

Adjuvant analgesics are commonly used to help manage bone pain, neuropathic pain, and visceral pain and, if desired or indicated, to reduce systemic opioid requirement. They are particularly important in treating neuropathic pain. Extrapolating from studies conducted in neuropathic pain, in non-cancer conditions, tricyclic antidepressants are believed to provide relief from neuropathic pain. Several antidepressants are known inhibitors of hepatic drug metabolism via inhibition of cytochrome P450 enzymes, especially CYP2D6. Tamoxifen is an estrogen receptor blocker commonly used in patients with hormone receptor-positive breast cancer. Tamoxifen undergoes extensive hepatic metabolism, and inhibition of CYP2D6 decreases production of tamoxifen active metabolites, potentially limiting tamoxifen efficacy. Clinical studies indicate increased risk of breast cancer recurrence in tamoxifen-treated breast cancer patients also treated with SSRI antidepressants versus those receiving tamoxifen alone. If concomitant use of an SSRI is required in a patient receiving tamoxifen, use of a mild CYP2D6 inhibitor (sertraline, citalopram, venlafaxine, escitalopram) may be preferred over a moderate-to-potent inhibitor (paroxetine, fluoxetine, fluvoxamine, bupropion, duloxetine).

Corticosteroids have long been used to relieve neuropathic pain syndromes. Corticosteroids have also been effective for treating bone pain due to their anti-inflammatory effects as well as relieving malignant intestinal obstruction.

Non-Opioid Analgesics

The non-opioid analgesics include NSAIDs and acetaminophen. Acetaminophen is analgesic and antipyretic but not anti-inflammatory. Recent attention has been drawn towards the relative limited efficacy and significant adverse effects of acetaminophen, particularly hepatic and renal toxicity. This concern is compounded by the inclusion of acetaminophen in a variety of prescription opioid preparations (e.g., hydrocodone or codeine) as well as in a wide selection of over-the-counter products. Due to concerns about liver...
toxicity, the NCCN Panel Members advise that acetaminophen should be used with caution or not used at all with combination opioid-acetaminophen products to prevent excess acetaminophen dosing.

The FDA recommends that patients be advised to limit daily acetaminophen intake to a maximum of 4 grams, and imposed a limit of 325 mg of acetaminophen per tablet, capsule, or other dosage unit in prescription products to reduce the risk of severe liver injury from acetaminophen overdosing, an adverse event that can lead to liver failure, liver transplant, and death. The FDA also requires a new boxed warning to communicate the risk of severe liver injury associated with acetaminophen to health care professionals. In addition, the companies are required to add a new warning about the risk of allergic reactions, including anaphylaxis, to the label of all prescription acetaminophen-containing products. In January 2014, the FDA recommended that health care professionals “discontinue prescribing and dispensing prescription combination drug products that contain more than 325 milligrams (mg) of acetaminophen per tablet, capsule, or other dosage unit.” Due to concerns of hepatic toxicity, the NCCN Panel suggests that providers consider limiting chronic administration of acetaminophen to 3 grams or less per day.

NSAIDs produce analgesia by blocking the biosynthesis of prostaglandins, inflammatory mediators that initiate, cause, intensify, or maintain pain. History of peptic ulcer disease, advanced age (>60 years old), male gender, and concurrent corticosteroid therapy should be considered before NSAID administration to prevent upper gastrointestinal tract bleeding and perforation. As prophylaxis for NSAID peptic ulceration, consider adding misoprostol or proton pump inhibitors. Well-tolerated proton pump inhibitors are recommended to reduce gastrointestinal adverse effects induced by NSAIDs. The FDA cautions that the concomitant use of an NSAID with aspirin may reduce the cardioprotective efficacy of aspirin, and concomitant use of an NSAID and low-dose (or cardioprotective) aspirin may increase the risk of gastrointestinal bleeding. The NCCN Panel recommends avoiding concurrent use or administering these agents separately.

NSAIDs should be prescribed with caution in patients older than 60 years of age or in those having compromised fluid status, renal insufficiency, concomitant administration of other nephrotoxic drugs, and renally excreted chemotherapy in order to prevent renal toxicities. The addition of NSAIDs to opioids has the potential benefit of reducing the opioid dose when sedation, cognitive function, or other CNS effects of opioid analgesic therapy become burdensome.

In patients at high risk for cardiac toxicities such as those with a history of cardiovascular disease or at risk for cardiovascular disease or complications, NSAIDs taken with prescribed anticoagulants, such as warfarin or heparin, may significantly increase the risk of bleeding complications. NSAIDs should be discontinued if congestive heart failure or hypertension develops or worsens. Naproxen and ibuprofen are preferred NSAIDS for individuals at high risk for cardiac toxicities.

The NSAID and acetaminophen prescribing guidelines are listed in the algorithms under Non-Opioid Analgesic (NSAID and Acetaminophen) Prescribing.

Management of Bone Pain Without an Oncologic Emergency

The clinical complications of bone metastases include debilitating bone pain, which tends to be most prominent with movement, pathologic fractures, spinal cord compression, neurologic complications, and hypercalcemia of malignancy. The term skeletal related events (SREs) refers to a constellation of skeletal complications including fracture, need for surgery to bone, need for radiation to bone, and spinal cord
Bone-modifying agents such as bisphosphonates and RANK (receptor activator of nuclear factor-kappaB) ligand inhibitors are primarily used for the reduction of overall SREs, clinical trials have established that these agents can have an analgesic effect on patients with metastatic bone pain from a variety of tumors. Clinical trials have demonstrated the palliative effects of bisphosphonates (e.g., zoledronic acid, ibandronate) and denosumab (RANKL inhibitor) on pain related to bone metastases. Recent randomized trials suggest that, compared with zoledronic acid, denosumab provides comparable palliation of existing bone pain and may be superior for preventing worsening of bone pain. Due to differences in patient populations and the methods for assessing bone pain, direct comparison of bisphosphonates to determine their relative effects on bone pain across studies is difficult.

Surgical and radiation treatment for bone metastases is performed to relieve local bone pain, provide stabilization, and prevent impending fracture or spinal cord compression. In some situations, interventions such as vertebroplasty/kyphoplasty provide a greater likelihood of return to ambulatory status than radiation alone. Identification of patients who have impending fractures and are referred to an orthopedic specialist for stabilization prior to fracture is important for optimal surgical pain management. Consultation with a pain specialist for interventional consultation is recommended to determine optimal management strategy for vertebral augmentation.

Ablative strategies such as radiofrequency (RF) ablation or US ablation may also be performed to reduce pain and prevent SREs. RF ablation of bone lesions has proven successful in pain management, especially for those failing to achieve adequate analgesia without intolerable effects. Several small studies have also demonstrated the palliative effects of high-intensity focused US (HIFU) treatment of bone lesions.

Physical and occupational therapy may also be beneficial in the prevention of complications associated with SREs.

**Management of Pain Due to Bowel Obstruction**

Malignant bowel obstruction is a common complication in patients with abdominal or pelvic cancers. The initial management of patients presenting with bowel obstruction includes evaluation of the etiology of the obstruction. While surgery, radiation, and chemotherapy is the primary palliative treatment for malignant bowel obstruction, patients with advanced disease or poor general condition who are unfit for undergoing these therapies may require other palliative measures to relieve distressing symptoms such as bowel rest, nasogastric suction, corticosteroids, and/or octreotide (see NCCN Guidelines for Palliative Care).

**Specialty Consultations**

Continued pain ratings should be obtained and documented in the medical record to ensure that the patient's pain remains under good control and goals of treatment are achieved. Specialty consultations can be helpful in providing interventions to assist with difficult cancer pain problems. The major indication for referral to a specialty service provider is if the pain is likely to be relieved or will help patients become functional in their daily activities. These modalities are delivered by a specialty service provider, and pain management is accomplished by establishing individualized goals and then providing specific treatment and education for patients. The specialties include physical/occupational therapy; psychosocial supportive services; psychiatric consultation; pain and palliative care services; substance abuse consultation if there are questions/concerns about medication.
Non-Pharmacologic Interventions for Cancer Pain Management

Integrative Interventions
Since pain encompasses physical, psychosocial, and spiritual dimensions, the treatment of cancer pain inherently requires integration of therapies inclusive of cognitive-behavioral interventions.

Use of nonpharmacologic integrative interventions (physical, cognitive, and spiritual) may serve as valuable additions to pharmacologic interventions. Physical measures include massage, use of heat or cold, acupuncture, acupressure, etc. Cognitive interventions are aimed at enhancing a sense of control over the pain or underlying disease. Breathing exercises, relaxation, imagery/hypnosis, and other behavioral therapies can be very useful. Attention should also be focused on psychosocial support and providing education to patients and families. All of these can greatly enhance patients’ sense of control as well as greatly reduce the family/caregivers’ feeling of helplessness. A meta-analysis of the effect of psychosocial interventions on cancer pain highlights the importance of a multimodal approach to the management of cancer pain. The integration of physical, psychosocial, and spiritual modalities should also be based on assessment of cultural considerations. In cancer care, there is growing interest in attention to spiritual needs and the existential concerns often associated with pain. Many patients hold cultural beliefs about such treatments, and home remedies, rituals, prayer, and other spiritual practices may be most helpful in relieving or coping with pain. Involvement of chaplains and other spiritual care providers is essential. Spiritual needs should be routinely assessed and spiritual care should be incorporated as a component of comprehensive pain management.

Patient-based educational interventions have a significant impact in providing pain relief. Skills training helps modify the patient’s experience of pain and helps patients acquire techniques of pain management such as deep muscle relaxation. Education teaches the patients and family/caregivers how to use analgesics correctly and how to address side effects or unrelied pain.

Interventional Strategies
Some patients experience inadequate pain control despite pharmacologic therapy or may not tolerate an opioid titration program because of side effects. Some patients may prefer interventional therapies instead of a chronic medication regimen. Interventional techniques have been demonstrated in some cases, to eliminate or significantly reduce the level of pain, and/or may allow a significant decrease in systemic analgesics. Interventional therapies that can be useful in the relief of cancer pain include nerve blocks, vertebroplasty, kyphoplasty, regional infusion of analgesics, RF ablation, and other techniques. The major indications for referral for interventional therapies include a patient suffering from pain that is likely to be relieved with nerve block (eg, pancreas/upper abdomen with celiac plexus block, lower abdomen with superior hypogastric plexus block, intercostal nerve, peripheral/plexus nerve) and/or in patients failing to achieve adequate analgesia and/or the presence of intolerable side effects. For example, a patient with pancreatic cancer who was not tolerating opioids or not receiving adequate analgesia could be offered a neurolytic celiac plexus block. Neurolytic celiac plexus block may offer some
improvement in pain control over systemic analgesics, but is generally associated with a reduction in adverse effects.\textsuperscript{188,189}

Regional infusion of analgesics (epidural, intrathecal, and regional plexus) minimizes the distribution of drugs to receptors in the brain, potentially avoiding adverse effects of systemic administration. The intrathecal route of opioid administration should be considered in patients with intolerable sedation, confusion, and/or inadequate pain control with systemic opioid administration. This approach is a valuable tool to improve analgesia for patients who have pain from a variety of anatomical locations (eg, head and neck, upper and lower extremities, trunk).\textsuperscript{190,191} However, due to the risk of catheter migration and infection risk, consider limiting the duration of use to several days.

Percutaneous kyphoplasty and vertebroplasty might be useful for the treatment of lytic osteoclastic spinal metastases or in cases of vertebral compression fractures or spinal instability for which surgery is not feasible or indicated. Vertebroplasty/kyphoplasty helps restore mechanical stability while reducing pain and neurologic symptoms.\textsuperscript{192-197} Ablation techniques may also be helpful for pain management in patients who receive inadequate relief from pharmacologic therapy. Additionally, these approaches could be considered for patients who do not prefer or are not indicated for receiving additional pharmacologic interventions or radiation therapy. Neurodestructive procedures may be used for well-localized pain syndromes (eg, back pain due to facet or sacroiliac joint arthropathy; visceral pain due to abdominal or pelvic malignancy). Ablation therapy (eg, RF ablation, US ablation) for bone lesions can also be helpful in reducing pain.\textsuperscript{163-169} See section on \textit{Management of Bone Pain Without an Oncologic Emergency} for more information.

Neurostimulation procedures have been suggested to be useful for painful chemotherapy-induced peripheral neuropathies, neuralgias, complex regional pain syndrome, etc.\textsuperscript{198}

Interventional strategies listed above are not appropriate if patients are unwilling or in patients with infections, coagulopathy, or very short life expectancies. Also, the experts performing the interventions must be made aware of any medications that the patient is taking that might increase bleeding risk (ie, anticoagulants [warfarin, heparin], antiplatelet agents [clopidogrel, dipyridamole], anti-angiogenesis agents [bevacizumab]). If this occurs, the patient may have to be off the medication for an appropriate amount of time prior to the pain intervention and may need to continue to stay off the medication for a specified amount of time after the procedure. Interventions are not appropriate if technical expertise is not available.

\textbf{Summary}

In most patients, cancer pain can be successfully controlled with appropriate techniques and safe drugs. The overall approach to pain management encompassed in these guidelines is multimodal and comprehensive. It is based on routine pain assessments, utilizes both pharmacologic and nonpharmacologic interventions, and requires ongoing reevaluation of the patient. The NCCN Adult Cancer Pain Guidelines Panel advises that cancer pain can be well controlled in the vast majority of patients if the algorithms presented are systematically applied, carefully monitored, and tailored to the needs of the individual patient.

*Data within this table were obtained using [http://www.clinicalpharmacology-ip.com](http://www.clinicalpharmacology-ip.com), all information accessed March 22, 2014. Drug-drug interaction severity levels are represented as follows:

- **Severe** - Avoid Using These Drugs Together (Level 1): The use of these medications together is contraindicated. Rare exceptions may exist.
- **Major** (Level 2): The use of these medications together may be contraindicated in a select group of patients. Further therapy and/or an alteration in therapy may be necessary to avoid or limit the potential for interaction. The patient should be monitored for possible manifestations of the interaction.
- **Moderate** (Level 3): The use of these medications together may result in unintended clinical effects. Depending on the clinical situation, alterations in therapy may be required. The patient should be monitored for possible manifestations of the interaction.
- **Minor** (Level 4): The use of these medications together does not usually result in clinically significant interactions. Alterations in therapy or monitoring are not usually required*.200

†Many chemotherapeutic agents produce immunosuppression that can be exacerbated by concomitant dexamethasone use (Minor); physicians should consider goals of care, rationale for dexamethasone use, duration of use, and other factors when considering use with other immunosuppressive agents.

‡ Studies have produced conflicting results.201-203

£ Alternate agents that have little or no CYP 450 2D6 activity include citalopram, escitalopram, fluvoxamine, mirtazapine, or venlafaxine. Conversely, an aromatase inhibitor might be selected.
